Another disturbing factor, the leakage current, has been eliminated by suitable spacing of the lead-in wire of the collector and that of the other electrodes, and by enclosing the whole tube in a vessel containing dry nitrogen. The insulation was found to be greater than 10^{12} ohms.

With regard to the output capacity and the multiplication factor of the multiplier tube, and the input capacity of the amplifier used, the voltage amplitude at the first stage of the amplifier has been calculated to be 50μv., a value which exceeds the natural noises of the amplifier (the thermal agitation and the shot-effect) by one order of magnitude. Experiments have proved the expected result and by observation of the output voltage (on the screen of a cathode ray tube) it has been possible to count the individual electrons.

Low-speed electrons generated in vacuum can be counted by the method described here *by vacuum processes* only. It is the first counting method of its kind.

Compared to the counting devices already known using the production of ions in a gas-filled space, our method has the advantage of extremely good resolving power, which is in principle limited only by the transit time of the electrons in the multiplier tube. The counting gives always reproducible data.

As a first and simple application of the new device, I used it for counting photons, and it proved to be very successful. The zero illumination effect was found to be 40 electrons/minute, a number which can be further reduced by suitable improvement of the working conditions. Corresponding experiments are in preparation.

Our experiments having proved that the cooling process did not alter the light sensitivity and multiplication factor of the multiplier tube, we are justified in applying the data to the light sensitivity and photo-electrical output of the cæsium photo-cell obtained by previous workers at room temperature. The counting rate[1] is 2 per cent in the red maximum. Thanks to the excellent quality of the cæsium, this value is better than those obtained by other photon-counting methods[2].

Naturally the method of electron-counting presented here is not restricted to the use of liquid air, It is possible to get similar results by the application of a multiplier tube that has emitting surfaces made of a material having an appropriate high work function. and which accordingly has a low thermal emission.

A detailed communication is in preparation.

Effects of Methylcholanthrene and Colchicine administered with Plant Extracts on the Rat

IN the course of investigations on the response of plants and of 'phytocarcinomata' to various carcinogenic hydrocarbons and other compounds having the phenanthrene nucleus[1,2,3], it was found that some of these substances had an inhibitory action on the general somatic growth of certain plants. It was also found that it was possible to restore the normal growth-rate of these plants by simultaneous administration of certain plant extracts.

Haddow, C. M. Scott and J. D. Scott[4] have demonstrated that certain carcinogenic hydrocarbons and other chemically related substances had a persistent or temporary inhibitory influence on the body-growth of the rat, when administered by intraperitoneal injection.

We tested the above-mentioned combined treatment of plants on animals by the following methods.

Two series of experiments were made, one in early summer and one in late autumn. We used albino rats (150 in all) weighing 50–60 gm. The animals were divided into different groups and treated as follows: one group was given intraperitoneal injections of 10 mgm. of methylcholanthrene dissolved in 2 c.c. sesame oil; the second group was given intraperitoneal injections of 0·03 mgm. of colchicine dissolved in 2 c.c. sesame oil. Other groups were given, simultaneously with the intraperitoneal injections of methylcholanthrene or colchicine, subcutaneous injections of 1 c.c. lettuce or mistletoe extracts[5]. Control groups were given corresponding quantities of either sesame oil alone by intraperitoneal injection, or one or the other of the two plant extracts alone, by subcutaneous injection. Finally, one group was left without any treatment.

TABLE 1.

Treatment	No. of animals	Average mortality rate (days)	Percentage increase in body-weight in 21 days	% weight of testis in relation to body-weight	Ascorbic acid content of liver per (mgm./100 gm)
Oil	23	Until the end of the experiments (60 days)	51 34	1·37	13 740
Methyl-cholanthrene	28	21	15 17	0·97	8 535
Colchicine	8	Until the end of the experiments (34 days)	36 62	1·76	11·291
Control	23	Until the end of the experiments (60 days)	48 64	1·50	11 472

Table 1 shows the principal results of the summer and winter experiments. It may be added, however, that while the results of the summer and autumn experiments agreed as regards the body-growth of animals treated with methylcholanthrene alone, there was a discrepancy in the effects of the simultaneous treatment with methylcholanthrene and the above-mentioned plant extracts; the inhibitory influence of the combined treatment being about the same in summer as that of methylcholanthrene alone, while in autumn the percentage increase of the body weight of the animals subjected to the combined treatment was about four times as great as that obtained in animals treated with methylcholanthrene alone.

TABLE 2.

PERCENTAGE OF ANIMALS WITH FAT DEPOSITS.

Numerals 0 to 5 indicate the degree of fat deposits: 0 = none, 5 = maximum

Treatment	0	1	2	3	4	5
Oil	100	—	—	—	—	—
Methylcholanthrene	6·6	—	6 6	26 8	20	40
,, + lettuce	46 8	20	6 6	6·6	20	—
,, + mistletoe	74 6	14 2	—	14·2	—	—
Control	100	—	—	—	—	—

The most striking effect of methylcholanthrene was, however, the deposit of fat formed on the surface of the different organs of the abdominal cavity. In extreme cases, these coatings of hard fat attained a thickness of 3–4 mm. Table 2 shows, moreover, that the formation of these fat deposits could be considerably reduced by simultaneous subcutaneous injections of the plant extracts.

Animals treated with colchicine did not show fat deposits at all.

Preliminary observations have further shown an increased rate of cell division in the animals treated by us with methylcholanthrene alone, as revealed by Prof. A. P. Dustin after an injection of colchicine. It seems that methylcholanthrene sensitizes a great number of cells to the action of colchicine, such as the histiocytes and certain parenchymatous cells (amongst others those of the thyroid and salivary glands).

Summing up the various observations made in the course of the present preliminary experiments, it appears that profound metabolic and probably hormonal changes are involved in the carcinogenic action of methylcholanthrene, long before any morphological signs of tumour growth can be detected.

Autonomous Rhythmical Activity of Sense Organs

LIKE the lateral-line organs of fishes and the receptors of the semicircular canals of the dogfish[1], the nerves supplying the ampullæ of Lorenzini in elasmobranch fishes exhibit a spontaneous discharge of impulses. The receptors of the lateral line can be excited to a higher frequency of discharge by a flow of fluid in the canal[2], and although there is no evidence that such a flow can actually occur except when artificially produced, the possibility cannot be entirely ruled out that some unidentified mechanical agency external to the receptor is responsible for the maintenance of a permanent state of excitation. Hoagland[3], indeed, has argued that the spontaneous activity of lateral-line organs is due to a ciliary activity of the hair cells. It is therefore especially significant that a capsule containing a group of ampullæ of Lorenzini, with the nerve supplying it, can be isolated from a pithed ray, and can continue to discharge impulses spontaneously for more than 24 hours.

The capsule, no larger than a match head, contains no muscular tissue, and there are no hair cells in the receptors[4]. The capsule with its nerve was completely freed from its surrounding tissue and mounted in a moist chamber with the nerve resting on a pair of electrodes leading to an amplifier and oscillograph. The nerve was cut down so as to leave only a few intact fibres. A record taken soon after the preparation was installed shows three impulse trains at frequencies 5, 8 and 9 a second. A record taken the next day, 24 hours later, shows the same three fibres discharging at 9, 9 and 10 a second. The preparation was not disturbed between the taking of the two records; indeed, the moist chamber was not opened, and the temperature remained at 12–13° C. The preparation ceased to function 36 ± 6 hours after it was removed from the fish.

Even if hair processes were present as some earlier histologists have maintained, it is scarcely possible that they should beat at a rate of 10 a second in so viscous a medium as the jelly contained in the ampullary canals.

This observation rigidly fulfils the conditions for the demonstration of an independent physiological rhythm and there can be little doubt, therefore, that the spontaneous discharge represents an autonomous rhythm of excitations within the receptor cells.

Secretory Elements of the Pars Nervosa of the Pituitary

UNTIL recently it had been widely held that the nervosa hormones pitocin and pitressin, or their antecedents, were elaborated by the pars intermedia and were, from there, transferred to the nervous lobe. However, De Lawder, Tarr, and Geiling[1] have demonstrated the presence of these hormones in the pars nervosa of the fowl's pituitary, where there is no possibility of contamination of nervosa tissue with that of a pars intermedia. Hence the hormones must be formed by the endogenous constituents of the nervosa.

Bucy and Ibanez[2] have demonstrated the presence of characteristic glial cells, nerve fibres and terminals in mammalian partes nervosæ. Bucy termed the glial cells pituicytes, and naturally suspicion has fallen on these as the secretors of the hormones[3]. I have demonstrated the presence of pituicytes in all classes of the vertebrates (a full report of this work has been submitted to the Linnean Society of New South Wales for publication). If the pituicytes are secretory, it is to be expected that the hormones would be present in the various groups of vertebrates. This is so[4]; pitocin, pitressin and pituicytes occur in Tetrapods and Teleostei, while in Elasmobranchs pituicytes and pitocin occur. Pitressin may be present, but in the small doses used to date, it has not been detected.

Cowdry[5] considers it possible that the nerve fibre terminals may be secretory. The tissue culture work of Geiling and Lewis[6], however, shows that pitressin, at least, cannot be secreted by these agents. They made cultures of mouse pars nervosa, and in doing so, inevitably separated each nerve fibre from its perikaryon in the supra-optic nucleus; thus Wallerian degeneration would occur. Pitressin was conclusively demonstrated fifty days after explantation, and the only characteristic elements present were "extensive networks of large cells resembling neuroglia cells". These were undoubtedly the glial pituicytes, so it may be said that very probably the pitressin was elaborated by these cells. No test was made for pitocin, but since the nucleus supra-opticus is sympathetic in character[7] and all the evidence points to the fact that the secretory activity of the nerve terminals of the autonomic system is confined to the production of acetylcholine or an adrenalin-like body[8], it does not seem likely that pitocin is secreted by nerve terminals, which suggests that it also is secreted by pituicytes.

Adrenal Cortex Differences in Male and Female Mice

THE letter from Miss Deanesly published in NATURE of January 8, and dealing with the adrenal of the mouse, contains several inaccuracies. I feel bound to correct one which is not open to argument. Miss Deanesly gives what purports to be a brief account of the relevant literature. She has omitted to include a paper published six months ago by Dr. E. S. Horning and myself[1], which records observations having an important bearing on the subject under discussion. This paper contains a section entitled "The So-called X-zone and its Significance", to which readers of NATURE interested in the subject are referred. The warning given therein, that the adrenals of mice of inbred strains may show abnormalities and should, therefore, not be used for the interpretation of histological changes in the adrenal of normal mice, has unfortunately not been heeded by Miss Deanesly. The paper also points out the inadequacy of the histological methods used by other workers, including Miss Deanesly, in the study of the adrenal gland of the mouse.

London. Jan. 11.

---

[1] Cramer, W., and Horning, E. S., *J. Path. and Bact.*, **44**, 633 (1937).

DR. CRAMER alleges "several inaccuracies" in my letter, but the only "inaccuracy" specified, is the failure to cite a paper by himself and Dr. Horning dealing with pathological conditions in the adrenals. It was obviously impossible to give a full bibliography of the subject, and reference was made to the more recent paper (Cramer and Horning, *Lancet*, June 1937). The main facts regarding the sex difference in the mouse adrenal are well established, and various histological techniques have been successfully used by different workers. No good purpose would be served by controversy on the subject in these columns. The size of the *X*-zone in the female may vary in different mice, but its presence is certainly independent of inbreeding or pathological conditions. The dwarf mice referred to in my letter are born from phenotypically normal parents carrying a recessive Mendelian factor, and their production is not dependent on inbreeding. Their interest lies in the congenital pituitary deficiency, to which one may reasonably ascribe the absence of the usual response of the adrenal cortex to castration.

Optimum Temperature of Formation of a Blood Clot

In the course of experiments designed for the practical purpose of finding the most suitable conditions for the assay of hæmostatic surgical dressings containing thrombin, we have encountered a blood-clotting phenomenon which is apparently new. Not all the thrombin present can readily be extracted from these dressings, so that a new method has to be used for the estimation, depending on the measurement of the amount of clot produced on the fabric by soaking in an excess of citrated blood under specified conditions, the whole specimen being subjected to micro-Kjeldahl nitrogen estimation after removing the unclotted blood by washing. The quantity of clot is measured in milligrams of nitrogen per sq. cm. of fabric.

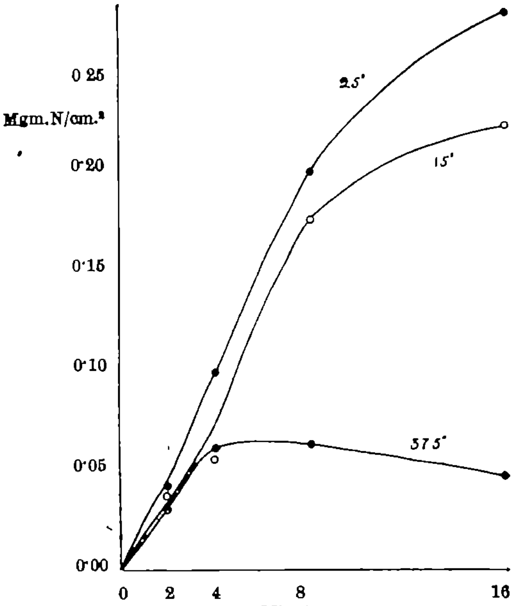

Fig. 1.

The relation of time to amount of clot at three temperatures. Points are means of five trials.

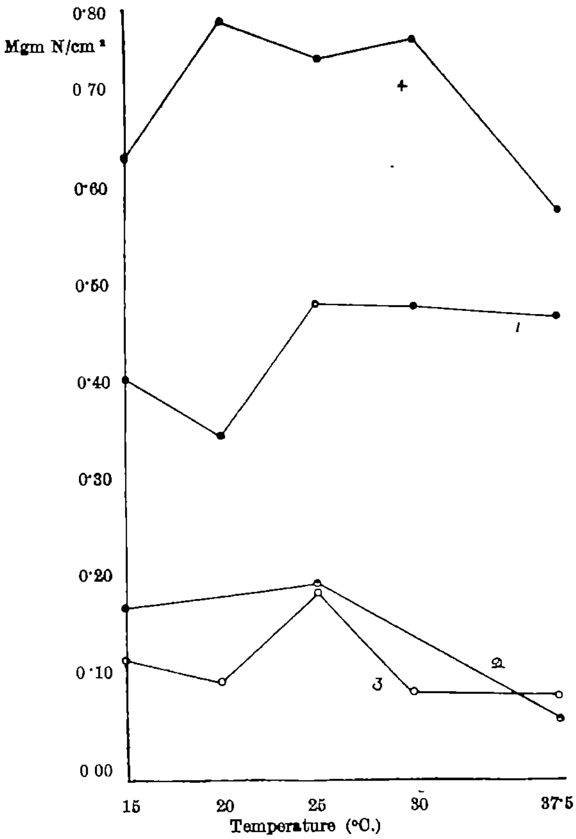

Fig. 2.

The relation of temperature to amount of clot. All determinations are at 8 minutes, and are means of five trials. Curve 2 is re-drawn from Fig. 1.

When, in addition to varying the time of soaking, different temperatures were used, we found that there was less clot at 37·5° C. than at lower temperatures, the maximum being at about 25°. Fig. 1 shows the results. The experiments were obtained from randomized blocks, and statistical analysis shows that the conclusion is significant. In order to obtain a self-contained confirmatory experiment, another series of tests were made, using five different temperatures. The 25° optimum was once more observed, and the difference between the trials at this temperature and at the higher temperatures is again statistically significant. A further trial (1, Fig. 2), using more heavily impregnated lint showed that in this case the optimum at 25°, although observed, is not pronounced enough to be significant, but it is important to note that 37·5° was certainly not an optimum. Yet another trial (No. 4, Fig. 2), using heavily impregnated lint washed in a large quantity of water and dried before testing, yielded an amount of clot at 37·5° which was significantly lower than at any of the three temperatures 20°, 25° and 30°, affording confirmation under widely differing conditions.

We do not consider that our results conflict at all with the numerous experiments showing that the maximum rate of clotting is at about 37·5°, since we are measuring the total amount formed—a different question. Our results are consistent with the view that two processes are proceeding together, one being clot formation by thrombin and the other an inactivation of the thrombin by the blood. If both processes have similar optima at about 37·5°, but different temperature coefficients, a peaked curve such as we find would result. In this connexion the 37·5° curve in Fig. 1 is illuminating, since the clot does not grow after the fourth minute, but actually becomes smaller, to an extent which is not significant from the statistical point of view, but may be real, and due to syneresis. Although some later workers have not found it, Landsberg[1] in 1913 reported a maximum clotting rate, under some conditions, at 25°, and our work appears to be confirmatory. There may be adaptive significance in the results, since clotting is normally required not in the recesses of the body, but at the surface, where the shed blood is not at 37·5° but at a lower temperature, whilst clotting in deeper and warmer positions is sometimes dangerous.

The details of the experiments will be published elsewhere.

d-Glyceric Aldehyde and Tumour Glycolysis

IT was found some years ago[1] that *dl*-glyceric aldehyde inhibits glycolysis of tumour cells. Anaerobic glycolysis is inhibited about 75 per cent by 10^{-3} M., whereas aerobic glycolysis is not affected by this concentration. Aerobically, it takes four times this amount to produce the same effect. Concentrations higher than 4×10^{-3} M. of the aldehyde are toxic.

In 1932 experiments were carried out with *d*-glyceric aldehyde kindly supplied by Dr. A. I. Virtanen of Helsingfors (Finland). As this compound was prepared by bacterial action on *dl*-glyceric aldehyde, there was some doubt as to its purity and we hesitated to publish our results. Now having obtained the pure *d*-glyceric aldehyde prepared synthetically by Prof. H. O. L. Fischer and Dr. E. Baer, of Toronto, to whom we are much indebted for a gift of the aldehyde, we were able to reproduce the results obtained five years ago, thus confirming the purity of Dr. Virtanen's preparation.

On April 19, 1932, we found that 10^{-3} M. of racemic glyceric aldehyde inhibited anaerobic glycolysis of Jensen rat sarcoma 74 per cent, whereas the same concentration of *d*-glyceric aldehyde gave only the slight inhibition of 11 per cent. With 2×10^{-3} M. we found inhibition of 91 per cent with the racemic and 33 per cent with *d*-glyceric aldehyde.

In recent experiments carried out with the new synthetic' preparation the following results were obtained :

INHIBITION OF ANAEROBIC GLYCOLYSIS OF RAT SARCOMA 39 BY GLYCERIC ALDEHYDE.

Conc of Aldehyde	Racemic	*d*
10^{-3} M	78 per cent	0 per cent
	68	8
	74	0
2×10^{-3} M.	95	33
	84	32
	92	38

INHIBITION OF AEROBIC GLYCOLYSIS OF RAT SARCOMA 39 BY GLYCERIC ALDEHYDE.

Conc. of Aldehyde	Racemic	*d*
2×10^{-3} M.	52 per cent	12 per cent
3×10^{-3} M.	66	18
4×10^{-3} M.	83	31

As the strong inhibition of tumour glycolysis found with small amounts of racemic glyceric aldehyde is not brought about by the *d*-component, the effect is obviously due to the *l*-form, which therefore should be at least twice as effective as the racemic. Lately some experiments have suggested the possibility that *l*-glyceric aldehyde may even be three to four times as active as the *dl*-form.

In this connexion it is noteworthy that J. Needham[2] recently obtained similar results in his most interesting experiments with *d*-glyceric aldehyde on glycolysis of chick embryo. We are able to confirm his results.

Addendum, January 3 : With a new sample of *d*-glyceric aldehyde, just obtained, no inhibition either of anaerobic or aerobic glycolysis was found with concentrations given in the above tables.

Drift of Net Assimilation Rate in Plants

IN reply to the letter from R. F. Williams[1], may I say that I much regret not having mentioned his paper[2] and that of Ballard and Petrie[3] in my note on the effect of age on net assimilation and relative growth-rates in the cotton plant[4], but I have just seen them for the first time. In stating that the absence of general trend of net assimilation rate up to time of flowering in my experiments was not *proved*, I was merely mentioning an inherent characteristic of the statistical test of significance. In testing the significance of a linear regression coefficient, the hypothesis is made that its true value is zero. This hypothesis may be disproved, at a given level of significance, in which case a significant general trend is shown, but it can never be finally *proved*. My results were clearly consistent with the hypothesis that the linear regression of net assimilation rate on time up to first flowering was zero, that is, that there was no general rise or fall, and it would seem, therefore, that to claim that my data confirmed the findings of Gregory[5] for barley was justifiable. Furthermore, my results agreed with those obtained for cotton by Crowther[6] in the Sudan, although no rigid statistical test was in the latter case applied.

With regard to the contention that the basis of estimation is important, it is worth noting that conversion of my data from a dry weight to a leaf area basis would introduce a rising tendency, since the area per unit leaf dry weight for the cotton plant falls somewhat in time[7]. If a significant upward trend were thus produced, my results for cotton would conflict even more markedly with the findings of Ballard and Petrie, and of Williams, that the net assimilation rate falls in time during the vegetative phase.

In using the term "flowering", Williams presumably refers to anthesis. So far as Gregory's results for barley are concerned, he claimed only that net assimilation rate was independent of time up to maximum leaf area, that is, for about the first six weeks, which corresponds with the stage of first differentiation of the flowers, not anthesis. After this point he also noted a rapid fall in net assimilation rate. For only one of the two experiments on oats described by Williams[2] does he appear to have obtained "unit leaf rate" data before six weeks, and in this case the rate appears to be remarkably constant up to 4–6 weeks. In so far as the cited experiments with temperate cereals are concerned, the results thus appear to confirm Gregory's findings. In the case of the single experiment with Sudan grass[3], the unit leaf rate appears to fall from the first observation (two weeks). It would be interesting to know the time of differentiation of flowers in this species.

The further interpretation of the data will be awaited with interest.

Blindness in Freshwater Fishes

THE cause of blindness in some rainbow trout was recently described by me[1] as being due to a trematode, *Diplostomum volvens* Nord., being present in large numbers in the lens of the eye. Since that date, two more lots of rainbow trout and one lot of roach have been examined, and in each case about five per cent of the fish were blind, due to a similar cause to that already recorded.

I have also been informed from a reliable source that the disease is well known in Holland and other countries of Europe. Further, my attention has been directed by the Hon. Miss M. Rothschild to further literature of the subject, particularly to a recent account of this trematode by Wesenberg-Lund in his work on freshwater fauna[2] which records that *Diplostomum volvens* Nord. does not possess a direct life-cycle from bird to fish but that the fertilized eggs, which pass out of a water bird, develop into a miracidium which penetrates a molluscan and there produces the asexual cycle generation of sporocysts. These in turn give rise to fork-tailed cercariæ, which in due course escape from the snail or first intermediate host into the water. It is at this stage that the worm enters the second intermediate host.

The cercariæ penetrate the skin of the fish and reach the lens of the eye via the blood stream; the final host invariably acquires the parasite by eating fish which have become infected in this way.

Density of Living Aquatic Organisms

FOR some reason, the determination of the density of aquatic organisms has always presented to biologists a really difficult problem. The usual method has been to kill or narcotize the organisms and find the rate at which they sank in a liquid of known density, or alternatively to find a liquid of such density that the organisms floated or rather just did not sink in it. The density of the liquid was taken as the density of the organism. Neither of these methods need, I think, be seriously considered further. They may be suitable for minerals but scarcely for living organisms.

There is a very simple and accurate method available and this is best described by giving an actual example. Three typical specimens of the common polychæte worm *Nereis diversicolor* were sent from Plymouth in a large jar of sea-water. They arrived in perfect condition. The jar was placed in a sink of cold water until the temperature was constant. A specific gravity bottle was cleaned, weighed and standardized. The bottle was then weighed full of distilled water at 7·4° C., which was the temperature of the water in the sink. It was then filled with the sea-water and weighed, and finally the three worms were introduced and the bottle again weighed.

The only remaining problem was then to find the exact volume of the worms. This was quite readily done by pouring the contents of the bottle after the last weighing into a 200 ml. flask. The worms were retained in a funnel with a small plug of glass wool. When practically all the sea-water had gone the worms were just rinsed with a little distilled water. (If this is thought objectionable a little isotonic solution of sodium nitrate could have been substituted, but actually this was quite unnecessary since the worms went straight back to sea-water and were alive after two days.) They were only in contact with the distilled water for a few seconds. The solution of sea-water in the 200 ml. flask was made up to the proper mark. We can call this solution *A*.

The same specific gravity bottle was then again filled with the sea-water and the contents washed into another 200 ml. flask. We can call this solution *B*. The two solutions have different concentrations which can be determined by a very simple titration with *N*/10 silver nitrate, which incidentally need be only approximately *N*/10. From these two titrations the exact volume of the worms is obtained. The accompanying figures give the density of *Nereis* fairly exactly. The last two figures should probably be disregarded since the density of *Nereis* must vary with such factors as the contents of the gut, etc., or the sex. Again, it represents the average density of the three worms. Finally, densities given to six places of decimals are meaningless unless the density of the distilled water has been redetermined since the discovery of heavy water.

Volume of S.G. bottle at 20° C. and 760 mm.	51·21 ml.
Weight of distilled water at 7 4° C.	51·4198 gm.
,, ,, sea ,, ,, ,,	52·8384 ,,
,, ,, sea-water plus *Nereis* at 7·4° C.	53·0733 ,,
Calculated density of sea-water at 7·4° C.	1·02766

Volume of *Nereis*. Titrations with silver nitrate *N*/10 : 14·35 ml.; 12 91 ml.

$$\text{Vol.} = 51{\cdot}21 - \left(\frac{12{\cdot}91}{14\ 35} \times 51\ 21\right) = 5{\cdot}14 \text{ ml.}$$

		gm.
Weight of sea-water displaced by *Nereis*	= 5·14 × 1·02766	= 5 2822
,, ,, ,, in bottle with ,,	= 52·8384 − 5·2822	= 47 5562
Weight of *Nereis*	= 53·0733 − 47·5562	= 5·5171

$$\text{Density of } Nereis \text{ at } 7\ 4° \text{ C.} = \frac{5\ 5171}{5\ 14} = 1{\cdot}07336.$$

The method is applicable to freshwater animals, but to find their volume they are placed in a 100 ml. flask and 25 ml. of a 1 per cent solution of glucose added. The concentration of the glucose is easily determined by MacLean's blood sugar test, while the solution of glucose is too weak to have any effect on osmotic pressure. Again, the rate of diffusion of glucose is far too low to have any effect on the tissues except perhaps on naked protoplasm itself.

The density of several living organisms has been determined in this way. Thus the density of the living three-spined stickleback at 10° C. was found to be 1·00286 swimming in Marlborough tap-water with a density of 1·00011 at the same temperature. The density of any living tissue can be determined in the same way provided a suitable Ringer solution is available.

Salaries in Soviet Universities

THE equivalent figures given in NATURE of December 11, p. 1007, namely, 1100 rouble = £42, are about three times too high on the actual purchasing power of these salaries. Sir Walter Citrine has published a thorough study of prices and standard of living in Russia[1], and finds the purchasing power of the rouble for food and necessities of life is equivalent to 3*d*. in England. This figure is confirmed by Andre Gide and Trotsky in recent books, and I have myself gone very thoroughly into the matter and would say that for January 1938 this is still not an unfair estimate[2]. On this basis the Russian salaries are as follows :

Directors of chairs in universities	=	average	£190	per annum.
Professors	=	,,	£175	,,
Senior lecturers	=	,,	£120	,,

First-year students, at 130 roubles per month, are paid the same as the mass of unskilled workers in Russia, equivalent to 8*s*. 4*d*. per week in Great Britain.

The services received free in addition to salary, while not negligible, are, owing to overcrowding, very much curtailed compared with our own as received by the poorer members of the community in England ; for example, the schools are usually run in two shifts per day and some even in three shifts.

Of the 542,000 students attending higher educational institutions, probably not as many as 5 per cent approach the standard of training and have the facilities we understand by university education; the rest receiving a training corresponding more to the higher forms of secondary schools, evening classes, etc.

Most of us would be glad to see a rise in the standard of living in Soviet Russia, but at present it is deplorably low, even more as regards wages than salaries.

Apparent Enlargement of the Sun at the time of Rising and Setting

I HAVE always thought that the accepted explanation of the apparent enlargement of the sun, moon and constellations near the horizon was that we look on the sky as a very shallow inverted bowl, and therefore look on the horizon as very much farther off than the zenith. The sun having the same angular diameter wherever it is seems a larger body when on the horizon because we apprehend it as being much farther off than when in a high altitude.

The experiment described by Mr. Trotter in NATURE of January 15 supports this. It is not necessary to wait for sunshine to repeat it ; look at an electric lamp until a retinal after-image is formed ; look at a sheet of paper held at reading distance and then hold it at arm's length ; the after-image will apparently increase in size.

There is another observation which bears on the same point. I have not seen it described and only noticed it for the first time last summer in Chichester Harbour : look down on to a perfectly still sheet of water at night ; the constellations near the zenith look absurdly small ; the mind places them on the surface of the water quite close at hand. To me the reflected constellations look only half the size of the real ones in the zenith.

Axial Spin of Arrows

THE correspondence referring to the feathering of arrows[1] recalls some seen at Parà about the beginning of the century in a collection of various gear and costume of the Amazon Indians. It would seem that these folk liked their arrows to spin, for at any rate some of them were feathered with fairly long narrow feathers, the tips of a pair were bound on opposite sides near the butt and again tied further along the shaft again on opposite sides but with a half turn ; so that one feather was on one side at the end and on the other further along. If memory serves me, many of the feathers were those of the 'arà' or macaw, of which, too, were made wonderful helmets or head-dresses.

Prof. Alfred Lodge

MAY I add a few words to the obituary notice of Alfred Lodge, written by one whom I count amongst my friends ? I had the privilege of being taught mathematics by Alfred Lodge, and although I was a mere boy at the time, I remember distinctly realizing my good fortune in having a teacher quite out of the ordinary. Whereas others taught us the usefulness of mathematics, it was Alfred Lodge who impressed on us its beauty. Under his influence one acquired the attitude towards any problem that it was not completely solved until one had found the neatest solution. Sometimes direct attack on a problem had led to a surprisingly simple result, and I remember how on such occasions Lodge would be asked either by a colleague or by a pupil if he could not find a more elegant derivation. It usually took him less than half an hour to produce it. The affectionate regard that we as schoolboys had for him was reflected in his nickname, "Daddy Lodge".

A New Monochromator

IN a letter published in NATURE of January 22, I described a monochromator based on the principle of interference of polarized light in a number of quartz plates, and some experiments carried out with such an instrument. From a private communication received from Dr. B. Lyot on January 29, I have learned that much the same principle for the construction of a monochromator was outlined by him in the *Comptes rendus* of the Paris Academy of Sciences in December 1933. Dr. Lyot did not plan to use Polaroid film in his construction, and has not yet completed an instrument according to his design. I regret the omission of reference to his work, with which I was unfortunately completely unaware when I wrote my letter.

Points from Foregoing Letters

A METHOD whereby ultracentrifugal sedimentation diagrams, giving the shape of the curve relating concentration gradient to distance from the axis, may be obtained by direct photography, is described by J. St. L. Philpot. The *Schlieren* principle is used together with a diagonal edge and cylindrical lens.

Prof. Z. Bay states that the sensitivity of the electron-multiplier tube with cæsium electrodes, when used as an electron-counting device, is greatly improved by cooling in liquid air, so that no spurious electrons shall be liberated by thermal agitation. Another disturbing factor, the leakage current, can be eliminated by suitable spacing of the lead-in wires and by insulation in dry nitrogen. The improved apparatus can be used for counting low-speed electrons generated in a vacuum, by vacuum processes only.

The effects of injection of the cancer-producing substance methylcholanthrene upon the body weight and metabolism of rats have been investigated by Dr. L. Havas and E. Gal. They find that this substance brings about fat deposition on various organs of the abdominal cavity. This effect can be counteracted to some extent by simultaneous injections of lettuce or mistletoe extract. Methylcholanthrene also brings about an increase in the rate of cell division and renders certain cells more sensitive to the action of colchicine.

A spontaneous discharge of impulses has been recorded by A. Sand from an isolated preparation of ampullæ of Lorenzini over a period of 24 hours. This furnishes complete evidence that these organs possess an autonomous rhythm of activity.

In support of his view that the hormones pitocin and pitressin (found in the pars nervosa of the pituitary) are secreted by special cells, pituicytes, M. Griffiths points out that the hormones are present in all classes of vertebrates where pituicytes are found. Since pitocin was found by Geiling and Lewis in tissue cultures of pars nervosa which were free from nerve fibre terminals, the latter cannot be responsible for the secretion of the hormones.

Referring to Dr. R. Deanesly's recent account of adrenal cortex differences in male and female mice, Dr. W. Cramer states that the adrenals of mice of inbred strains may show abnormalities, and should, therefore, not be used for the interpretation of histological changes in the adrenal of normal mice. Dr. Deanesly considers that, although the X-zone in the female may vary in different mice, its presence is independent of inbreeding or pathological conditions.

R. Maxwell Savage and W. P. Chambers show that the size of blood-clots formed by thrombin-impregnated cotton is at a maximum not at body temperature but below it. They attribute this to differences in the temperature coefficients of clotting and inactivation, and suggest that it is one of the adaptive mechanisms by which intravascular clotting is avoided, since normally clotting is required in shed blood at about the optima found.

Dr. B. Mendel, F. Strelitz and D. Mundell report that, unlike the racemic *dl*-glyceric aldehyde, the dextro-rotatory form, *d*-glyceric aldehyde, does not inhibit the transformation of glycogen to lactic acid by tumour cells. This confirms results of unpublished experiments carried out several years ago by the authors with *d*-glyceric aldehyde obtained by the action of bacteria upon the racemic form. The inhibition of glycolysis is apparently to be ascribed to the lævo form, the activity of which may be several times as high as that of the *dl*-form.

Replying to a letter from R. F. Williams on the time drift of net assimilation rate in plants, O. V. S. Heath points out that a re-examination of the published data of Williams and of Ballard and Petrie indicates that their contention of a fall in net assimilation rate before flowering does not apply to the first six weeks (flower differentiation) in the case of temperate cereals. This is precisely what Gregory found for barley, while Heath himself found no fall in cotton before first flowering.

Referring to his recent note on the blindness of freshwater fishes caused by the trematode *Diplostomum volvens*, Dr. W. Rushton quotes further references indicating that the parasite does not possess a direct life-cycle from bird to fish, but passes as an intermediate stage through a mollusc, where it produces the asexual cycle generation of sporocysts.

A. G. Lowndes describes a simple indirect method for determining the specific gravity of aquatic organisms. It employs the usual specific gravity bottle and determines the volume displaced by the organism by chemically titrating some constituent present or added to the water, for example, chlorine in sea water or glucose added to fresh water.

Research Items

Duration of Life in Prehistoric Man

DR. HENRI V. VALLOIS, in view of the fact that the age of the individual in the study of skeletal remains of prehistoric man has been treated as a matter of secondary importance, has endeavoured to arrive at a more precise statement of the facts on the recorded evidence and in the light of a personal examination of a number of the specimens (*L'Anthropologie*, 47, 5–6). Of two criteria of age, the evidence of the teeth and the closure of the sutures of the cranium, the latter is taken as the more generally trustworthy and suitable for this purpose. The evidence is classified as Neanderthal, upper palæolithic and mesolithic. On the whole, the striking fact emerges that the life of fossil man was short. Of one hundred and eighty-seven subjects of determinable age, 55 per cent Neanderthal, 34·3 per cent upper palæolithic and 37 per cent mesolithic subjects died before reaching the age of twenty years; while of the remainder, the majority, 40 per cent Neanderthal, 53 per cent upper palæolithic and 58·5 mesolithic, died between twenty and forty years. Of the remaining sixteen, 5, 10·8, and 1·5 per cent respectively died between forty and fifty years, while only three survived the age of fifty years. Yet even these three had not attained true old age, as important sutures were still not closed. In addition to the numbers given above, there were thirty-one specimens for whom it was not possible to determine the exact age; but of these nineteen were not yet adult, and it is practically certain that the remaining twelve had not attained old age. These additional specimens bring the total up to 218. Notwithstanding defective evidence, there would appear to be a marked increase in the duration of life in the Bronze Age and among the Egyptians of the Roman period. In the fossil groups, man appears to have lived longer than woman. Especially below the age of forty is feminine mortality higher. As regards the cause of the early mortality, so far from civilization having shortened the natural span of life by 'dysharmonics' as Metchnikoff thought, it appears to have lengthened it.

Easter Island Inscriptions

DR. A. MÉTRAUX, Bishop Museum fellow, figures and describes in *Man* of January two inscribed tablets and an inscribed fragment from Easter Island, now in the Bernice Pauahi Bishop Museum, Honolulu, which have not been recorded by those who have written previously on the subject of the Easter Island inscriptions. Sixteen authentic tablets deposited in various institutions are now known. Most of these have been described. When the Easter Island tablets were first discovered the islanders were perfectly willing to part with them; but the modern natives, realizing the interest taken in them by Europeans, have manufactured imitations. The tablet acquired by the British Museum in 1903 is probably modern in origin. The signs are poorly engraved and suggest the style of modern artists. Faked tablets were made in the island even prior to 1882, as witness a faked gorget in the Australian Museum. The two tablets of the Bishop Museum are in poor condition, the wood being partly rotted away. Signs appear on one side only, the other side being decayed. The best preserved specimen is twelve inches long, three and three-quarter inches wide and three-quarters of an inch thick. The signs are incized according to the best classical tradition. The symbols have been engraved with an obsidian or shark's tooth point. The signs form eleven rows; of the characters, one hundred and twenty are legible. The rows of signs are reversed alternately. The second tablet, twenty-seven and a half inches long, three and a quarter inches wide, and one inch thick, contains twenty-five unobliterated signs around a natural hole in the wood. A few years ago it was suggested by Mr. de Hevezy, a Hungarian linguist, that there were striking and incontrovertible parallels between the Easter Island script and the Indus Valley inscriptions from Mohenjo-daro and Harappa. It is now shown that the resemblances were due to inaccurate reproductions of both groups. The only resemblances are simple geometrical signs. The Hungarian author suggested that the Easter Island signs might be thousands of years old; but the largest tablet in existence in the Museum of Brain-Lecombe is carved on a European oar.

Effectiveness of Administered Hormones

THE preparation in pure form of the products of those endocrine glands which produce chronic effects in the body, has had the untoward result of making more difficult the experimental or therapeutic imitation of their actions. The hormones of the gonads, anterior pituitary and adrenal cortex and insulin appear to be utilized or eliminated soon after they enter the circulation, and in these circumstances their physiological effectiveness depends very largely on the method by which they are administered. Thus, a given dose of œstrone in aqueous solution is known to be more effective if given in a series of divided doses than when given in a single large dose; similarly, esterification of œstrone and of androsterone and testosterone has been found to increase their activity; but whether this increase in activity was due to delayed absorption or to slow hydrolysis after absorption was not clear. Drs. Deanesly and Parkes (*Proc. Roy. Soc.*, B, 124, 279; 1937) have recently studied the variations in effectiveness of a large number of gynæcogenic and androgenic compounds brought about by different methods of administration, involving subdivision of the dose, the nature and volume of the solvent, the addition of fatty acid, esterification and mode of administration. It is clear that the increased effectiveness of the esters is due to delayed absorption from the site of injection, since they are no more effective than the free hormone, when both are given intravenously. The esters are most effective when given in such a form that they might be expected to crystallize out in the tissues, and this finding led the authors to investigate the effects of giving the hormone by subcutaneous implantation of crystals or compressed tablets. This method was found to be extremely effective. A further advantage of the method is that, at the end of the experimental period, the tablet can be removed and weighed, and a reasonably accurate determination made of the actual amount of hormone absorbed.

Control of the Bed-bug

THE common bed-bug, *Cimex lectularius*, has spread during recent years to an extent that probably about four million people in Greater London alone are, to some degree, troubled by this pest. Slum clearance campaigns have caused the demolition of many bug-infested quarters. Unfortunately, in many instances precautions were not taken to eradicate the bed-bugs before the families moved into their new homes. The result has been that new colonies of the insect have been founded and new areas, formerly free from the pest, have now become infested. Probably the chief means of dissemination is the carriage of bed-bugs in furniture and bedding, but there are many other methods of lesser importance. While bed-bugs do not transmit any actual disease in Great Britain, the constant irritation due to the injection of minute doses of the insects' saliva into the blood is likely to contribute largely to the ill-health of children and even sometimes of adults. The habits, behaviour and means of control of this insect are dealt with in a pamphlet on the subject, entitled "The Bed Bug" and issued by the British Museum (Natural History) as No. 5 of the Economic Series. This pamphlet, which is in its fourth edition (1937), is written by Mr. A. W. McKenny-Hughes, assistant keeper in the Department of Entomology. It is obtainable either from the Museum or through booksellers, price 6*d.*

Genitalia of Hymenopterous Insects

THE attention of students of insect morphology is directed to a paper by Mr. O. Peck (*Canadian J. Res.*, 15*D*, 221; 1937) which embodies an illustrated account of the structure and supposed homologies of the male genitalia in the Hymenoptera. Four main components are distinguishable in these organs. (1) An annular basal gonocardo which bears a pair of claspers (2), and each of these latter carries an inner clasper or volsella (3). A median organ or ædeagus (4) with a pair of lateral parameres or sagittæ are supported by the claspers and volsellæ. The true homologies of these parts are very uncertain and have not as yet been definitely established. The remainder of the paper is devoted to a detailed study of the male genitalia of the Ichneumonidæ in particular. This account is to be completed in a later issue of the *Journal.*

Anatomy of Protobranchs

PROF. HAROLD HEATH in his paper "The Anatomy of some Protobranch Mollusks" (Mémoires du Musée royal d'Histoire Naturelle de Belgique, deuxième série, fasc. 10, 1937) shows several important points in connexion with the comparative study of various species belonging to six genera obtained from both Atlantic and Pacific coasts: *Nucula* (10 species), *Acilia* (4 species), *Yoldia* (8 species), *Yoldiella* (2 species), *Malletia* (one species), *Leda* (6 species). It is shown that the muscular system in all is very similar, the pedal muscles especially being complicated. It is interesting that differences exist between the specimens of *Yoldia thraciæformis* from the Atlantic and Pacific, the western representatives being considerably smaller than the eastern, yet all are sexually mature, and the larger individuals possess certain small muscles in the vicinity of the anterior adductor which are apparently not present in the smaller form. In studying the digestive system, the author finds that the simplest types of intestine occur in *Nucula* and *Acila* from shallow water, between 5 and 125 fathoms, whilst in the deeper water species of *Nucula* it is much more complicated. However, *Yoldia, Yoldiella, Malletia* and *Leda* possess intestines of the same relative length and with the same arrangement in species from all depths ranging from 11 to 1569 fathoms. There thus appears to be in *Nucula* a correlation between length of intestine and depth; but it is carefully stated that too few specimens have been examined as yet to be quite sure of the fact. "If such be the case it may be that nutritive material diminishes according to depth and that complete digestion and absorption of food demands correspondingly elongated intestines".

Vitamin C in the Potato

FOLLOWING the publication by Ijdo of work on the vitamin C content of different varieties of potato (cf. NATURE, 140, 977–78; 1937), A. M. Smith and W. Y. Paterson record in the *Biochemical Journal* (31, 1992–9; 1937) results which confirm and extend those of the Dutch investigator. These authors examined a large number of tubers, from the 1935, 1936 and 1937 crops, for ascorbic acid, using the usual method of extraction with trichloroacetic acid and titration with 2 : 6-dichlorophenol-indophenol, and also a modification of it suitable for rapid routine testing. They found that the vitamin C content varied with the variety of potato and with the time and temperature of storage, but was independent of size and weight of tuber, of environment, including soil conditions and manuring, and possibly season. They also discovered that the content was significantly higher in tubers suffering from mosaic disease or leaf-roll. Therefore, determination of ascorbic acid in potatoes affords not only a method of identifying variety, but also of testing the presence of virus disease, under uniform storage conditions. The test should assist growers in selecting stock seed for the next season's crop.

A Criticism of Warnstorf's "Sphagnologia Universalis"

As the result of a visit to the Warnstorf Herbarium at Berlin-Dahlem, A. le Roy Andrews expresses his opinion that the Warnstorf "Sphagnologia Universalis" is "inflationary" and needs drastic revision (*Ann. Bryologici*, 9, 1936. Leyden. British agents, Dawson, London). As a new and simplified classification Andrews suggests that the two main sections (termed sub-genera by Andrews) *Inophlœa* (*Cymbifolia*) and *Litophlœa* (the other groups), which date back to Russow, still stand, but the sub-sections of these according to Warnstorf appear to be of unequal rank. Andrews separates *Rigida* under Müller's name Section *Malacosphagnum* from the remaining groups which fall under Section *Acisphagnum*. As a result of careful comparison, it is also suggested that Warnstorf's eight groups of *Litophlœa* (exclusive of *Rigida*) may justifiably be reduced to three: A. Series *Squarrosa*, B. *Cuspidata* (including *Subsecundum*, which appears to have no fundamental distinction from *Cuspidata*) and C. *Acutifolia*. This classification is based on the usual characters of leaf section, pores, etc., in conjunction with certain features of specialized stem leaves and perichætial leaves. Andrews points out that the presence or absence of fibrils needs to be used with caution, as also the degree of exposure of chlorophyll cells; the latter, as shown by Russow, have equal exposure at both surfaces in initial stages and only reach unequal exposure during subsequent development. In Warnstorf's "Sphagnologia" 342 *Sphagnum* species are described and to these subsequent additions have been made. Andrews doubts that any really critical student could confirm at most more than a 100 good species.

Antirrhinum Rust

A SEVERE infection of antirrhinum plants in 1934 by the rust fungus *Puccinia antirrhini* stimulated the prosecution of much intensive research on the disease by D. E. Green, mycologist to the Royal Horticultural Society. The text of a lecture which reviewed these investigations is now published in the Society's *Journal* (62, Pt. 12, pp. 530–537, Dec. 1937). Antirrhinums in Canada, California and Bermuda have been attacked very severely by the fungus for a decade or more, but the disease had not been reported from Europe prior to 1933. Uredospores are produced, and also teleutospores, which, however, have not been found to re-infect snapdragon plants. The method of overwintering is still a problem, but the most obvious means would appear to be persistence of the fungus in perennating antirrhinum plants in frost-free localities. Uredospores appear thereon in the following summer, and infect other plants. Spraying is an exorbitant and economically ineffective control, but Mr. Green's lecture ended with an account of progress with rust-resistant snapdragons. Some American strains can claim 70–90 per cent resistance, largely at the expense of their horticultural beauty, but the results of work in 1937 at the Society's gardens at Wisley show that a number of more attractive strains obtained by crossing have achieved 50–75 per cent resistance.

Leaf Diseases of *Narcissus*

DR. P. H. GREGORY has collected information upon diseases of *Narcissus* leaves, in the Royal Horticultural Society's Daffodil Year-book for 1937. *Narcissus* leaf scorch is caused by the fungus *Stagonospora Curtisii*; white mould results from the activities of *Ramularia Vallisumbrosæ*, whilst a grey mould is induced by *Botrytis narcissicola*. *B. polyblastis* is responsible for the condition known as 'fire'. *Narcissus* 'stripe' is probably caused by a virus. Symptoms, life-histories and control are described from a horticultural aspect, and the paper should prove a useful review for the practical grower.

New Zealand Earthquake of June 17, 1929

MR. J. HENDERSON, the director of the New Zealand Geological Survey, has written a detailed report on this earthquake (*N.Z. J. Sci. and Tech.*, 19, 65–144; 1937). Its origin lay near Murchison along a fault directed a few degrees east of north. During the earthquake, the crust on the east side rose over a length of about five miles, especially where the fault crosses the Buller River. A few years before, bench-marks were laid along the railway line of the district. They were re-observed in August 1929, and again in March–July, 1930. The first measurements showed that, to the west of the fault, there was an uplift of 5 ft., dying out within one quarter of a mile. At the fault itself, the uplift of the east side was 14 ft. 9 in., rising to 16 ft. in about a mile, and decreasing irregularly to zero at a distance of about 15 miles. The interval between the two surveys was marked by a general settling of the crust in four blocks. In that nearest the fault, about one mile wide, the changes were small. The next, about three miles across, was uplifted, at one point by 3 ft. 3 in. In the third, five miles wide, the crust sank uniformly by about 18 in.; while, in the fourth, of slightly less width, the subsidence decreased from about 17 in. to zero. The only evidence of horizontal displacement was provided by shifts in the railroad near the fault. Three points on the west side were moved about 4 in. west; while, on the east side, the average movements of five points were 9 ft. 5 in. north and 7 ft. 10 in. west. The terminal stations on the west side, distant 242 yards, are now nearly 6 in. farther apart, while those on the east side, distant 594 yards, are now nearer by 27 in.

Crystal Structure of Uranium

THE X-ray powder diagrams of uranium found by C. W. Jacob and B. E. Warren (*J. Amer. Chem. Soc.*, 59, 2588; 1937) indicate that the structure can be considered as a deformed hexagonal close-packed structure with four neighbours closer than the other eight. From its position in the periodic table, it might be suspected that uranium would have the body-centred cubic structure of chromium, molybdenum and tungsten, but this is not the case. It is also found that the densities of chromium, molybdenum and tungsten, when plotted against the atomic numbers, fall on a smooth curve, whilst uranium is off the curve. The structure of uranium is quite different from that of any other element. The only element which is in the same column of the periodic table and shows any relationship to uranium is neodymium, which crystallizes in the close-packed hexagonal system. The structure of uranium is essentially that of a pseudo-metal such as antimony or gallium. The four closest neighbours in the crystal structure indicate a tendency to form four covalent bonds.

Compensation of Spherical Aberration in Telescopes

C. R. BURCH has recently published a paper (*J. Brit. Astro. Assoc.*, 48, 3, January 1938) in which he describes his experiments with an under-corrected Newtonian telescope, of aperture 9½ in. He cancelled the spherical aberration by means of a compensating plate—a "pseudo-plane-parallel" glass plate having spherically aberrant surfaces, placed at a suitable distance in front of the eyepiece. When this compensator was in its best position, stellar images at focus appeared appreciably smaller and lunar detail appeared sharper. While Mr. Burch does not suggest that compensators should be used for imperfectly figured mirrors, nevertheless as compensators of the low power required are easy to figure, they might prove extremely useful. During the discussion, Mr. F. J. Hargreaves suggested that a compensator mounted in a tube with rack and pinion might be utilized to allow for changes in spherical correction occurring during observing. Capt. M. A. Ainslie remarked that he had once utilized the spherical aberration of an ordinary biconcave lens, mounted a few inches in front of the eyepiece, to compensate for under-correction, the spherical aberration of the lens being opposite to that of the mirror. Those who use reflectors should read the paper and also the account of the proceedings of the meeting. They will derive a considerable amount of useful information on methods for dealing with under-corrections.

Science in India

ONE of the many happy results of sending a delegation from the British Association to the Silver Jubilee Session of the Indian Science Congress Association has been to arouse among the universities and scientific institutions in Great Britain a wider interest in the scientific work of India. As most of the delegates have now returned, the British Association may perhaps provide an opportunity for some of them to speak upon this subject, but meanwhile a good impression of the Congress can be gained from two of its publications that have now reached this country; namely, the *Proceedings*, and the "Outline of the Field Sciences of India"—volumes which correspond in a general way with publications of the British Association.

The "Outline" contains admirable accounts of the natural conditions of India and it is hoped that copies may be readily obtainable by scientific libraries. Dr. C. W. B. Normand begins with a concise account of the weather of India, in which he sets out clearly the phenomena of the monsoons that play so large a part in Indian life. The surrounding oceans are described by Lieut.-Colonel Seymour Sewell, and the geological history by Mr. D. N. Wadia: both chapters are full of information and in a short compass give the reader a clear idea of the physical environment, while Mr. Calder, Dr. Srinivasa Rao, and Sir Bryce Burt deal respectively with the flora, the fauna and the agriculture. Accounts of the racial ethnology and of the archæology by Dr. B. S. Guha and Rao Bahadur Dikshit complete an unusually interesting volume.

The *Proceedings* give a general impression of the extraordinarily wide range of subjects discussed by the Congress. As in the British Association, there are thirteen sections, though they are not identical in the two organizations, the Indian Congress including sections on entomology, medical research, and veterinary research, but not on economics, engineering or education. Well over eight hundred papers were presented: more than two hundred of these went to the chemistry section, while physics and medical research each had just under one hundred. Some of the laboratories from which this work has come are of course well known in Great Britain: Calcutta, Dacca, the various colleges at Madras, Bangalore, Allahabad, Bombay, Benares, but on looking through the volume one sees the names of other laboratories not yet as well known but where, nevertheless, much research activity is being shown.

This wide distribution of the research habit in the Indian colleges and universities is perhaps the most pleasing feature that emerges from a study of the volume. Western science has not simply been admitted into Indian universities; it has been taken up with eagerness and pursued by the Western method of experiment, observation and deduction. The extent of the development is all the more remarkable because of its recent growth: the founder of Indian chemical study, P. C. Ray, is still living, and the first experimental biologist, Jagadis Chandra Bose, has only recently died. Scientific investigation is very largely a modern activity in India, and there has been insufficient time for the evolution of a tradition of scientific work such as exists in the older laboratories of Great Britain, yet already men like Venkata Raman, Meghnad Saha, Birbal Sahni and others have made notable contributions to science and there are a number of younger ones whose work is full of promise for the future.

Hitherto it has been customary at the Indian universities to cast the net very widely, and the impression one obtains both from seeing the work and from perusing these summaries is of extensive rather than intensive investigation. Now that scientific work has begun to flourish so vigorously, it will become possible for the best of the leaders to impress their own high standards on their enthusiastic followers, and so ensure that Indian science may take its proper place in the laboratories of the world. There are, of course, many difficulties to be faced and overcome, but the results already achieved show what can be done, and it remains now to ensure to the gifted Indian worker the best conditions for development and for self-expression.

E. J. RUSSELL.

SOURCES OF ENERGY OF STORMS

The general theme of Dr. C. W. B. Normand's remarks in his presidential address to the Physics and Mathematics Section may be summed up as the thermodynamical approach to the study of storms.

At the basis of it all, following Margules, there is the simple enough proposition: if the whole air-mass around and including a storm can be circumscribed and considered as a closed system, it should be possible from a study of the initial and final conditions alone to decide the main source of the kinetic energy that has been created and displayed during the storm's existence. Before either the gravitational or the internal energies can decrease within a closed system, the stored-up energy must be present in a state of instability, actual or potential. The possible diversities of instability are believed to be composites of three main kinds, which for brevity are called the vertical, horizontal and latent types, the latter referring particularly to the instability that may arise from the latent heat of water vapour. Horizontal instability arises when two air currents of different temperature meet, as, for example, polar and tropical air. The horizontal and latent types are the two that can store up energy until favourable conditions allow its release. Latent instability develops behind a veneer of stability. It is analogous to the energy of a hydrogen balloon caught in the corridor of a large hall where it can be fed with more and more hydrogen but cannot escape up to the dome until given a relatively small, yet distinctly appreciable, push.

How are we to estimate quantitatively the relative importance of these main types of instability in originating storms? The standard method of attack is that of Margules, which, however, can be clarified and extended by graphical methods. The temperature-entropy diagram is chosen, with mass as a third co-ordinate. Solid models were shown, of which the volume represents the total energy available from a closed system, wherein all the elements rearrange themselves in the most efficient manner thermodynamically while passing from the initial unstable to the final stable configuration. In two simple examples of horizontal instability, one with discontinuous and the other with continuous change of temperatures, the volumes take the shapes of a wedge and a pyramid respectively.

The energy of a closed system in which latent instability alone is operative, can also be represented by the volume of a solid figure. Imagining a very extreme example and illustrating it by models, Dr. Normand stated that the average available energy may give rise to velocities of as much as 80 miles an hour, when the effect of rain on the descending air is neglected, and to a hurricane of 115 miles an hour throughout the mass, if full advantage is taken of the chance to saturate the descending air by the simultaneously falling rain. The atmospheric engine does not possess this ideal degree of efficiency but these calculations show how important latent instability may be, especially in the tropics.

The application of these ideas to dust-storms, thunder-storms and cyclones was briefly discussed. More field work is required to settle even the primary thermodynamical questions that should precede any full discussion of the dynamics of storms. The required upper air data must include reliable observations of humidity or of wet-bulb temperature as well as of air temperature. The Bay of Bengal, with its tropical cyclones, is ever a challenge to meteorologists in India.

MAGNETISM RELATING TO CHEMISTRY

It is only within recent years that the magnetic properties of matter have attained the same order of usefulness as the electrical ones in the solution of chemical problems. Recent advances in this subject formed the topic of Prof. S. S. Bhatnagar's presidential address before the Chemistry Section. From the point of view of nuclear chemistry, the nuclear magnetic moments are of considerable importance to theories of the 'neutron-proton' constitution of nuclei.

The actual values of the nuclear moments, however, are very small relative to those arising from the orbital momentum and spin of the electrons, and the main part of the magnetic moments of free atoms and molecules thus arises from the motion of the electrons around the nucleus. The magnitudes of these moments can be determined directly with the help of the atomic and molecular beam deflection methods and the results have been found to be in agreement with theoretical predictions based on spectroscopic evidence. For example, oxygen atoms obtained in their normal ^3P state from an electrodeless discharge are found to have a moment of 1·67 Bohr magnetons; while similarly the magnetic moment of the iron atom has been found to be 2·03 Bohr magnetons. The paramagnetism of oxygen, sulphur and selenium vapours shows that the ground states of these molecules are triplet in character.

In liquids and solids, the magnetic properties of the free molecules are greatly affected by interaction with neighbouring molecules, but in special cases like the rare earths this effect may be very small on account of the deep-seated nature of the electronic orbits from which the paramagnetism arises. Magnetic susceptibilities have been found to vary along the different axes of a crystal and this has been made the basis of an auxiliary method for determining their structure. Thus, for example, the high diamagnetism of graphite in the direction normal to the basal plane is to be expected from its layer lattice structure.

Pascal's discovery that the diamagnetic susceptibilities of many organic compounds are an additive property shows that the atomic orbits are but little distorted by the molecular bonds, and deviations from additivity can be used to establish different electronic structures. Attempts have been made to extend this to electrovalent salts by considering the molecular susceptibility to be the sum of the ionic susceptibilities. It has been established that the ionic susceptibilities of the elements of the first transitional series arise from spin alone, the orbital momentum being completely inoperative for copper and manganese ions, though it does not seem to be altogether quenched for nickel and cobalt. In the rare earth ions, on the other hand, the contribution of the orbital momentum to the paramagnetism of the ions is appreciable since it arises from inner protected shells.

While the ions of the transitional metals of the first series are paramagnetic, some of the complex salts formed from them are diamagnetic, indicating that during the process of co-ordination, the unpaired electrons of the outer shells become paired and a closed (inert gas) configuration results. If the paramagnetism does not disappear, then the complex is presumed to be held together by weak electrovalent forces, for example, $Cu(NH_3)_4$. The recent application of this method to the elucidation of the structure of some constituents of the blood is of considerable interest. It has been shown from magnetic measurements that the oxygen molecule undergoes a profound change in electronic structure on attachment to hæmoglobin, and that the bonds from the iron to the surrounding atoms are ionic in hæmoglobin and covalent in oxyhæmoglobin and carbon monoxyhæmoglobin.

Magnetic measurements have also yielded valuable information regarding the existence of 'free radicals' and have made it possible to distinguish them from dimeric molecules. Information about processes of polymerization has been obtained from observations of the changes in mass susceptibility, and compounds have been detected in systems of alloys by the same method. It also appears that magnetic fields can influence the rate of chemical reactions if the total molecular susceptibility of the products differs from that of the initial substances.

STRUCTURE OF THE HIMALAYA AND OF THE NORTH INDIAN FORELAND

Geological work carried out during the last few years, which was discussed by Mr. D. N. Wadia in his presidential address to the Section of Geology, has thrown much light on the structure of Northern India, a region of extraordinary geotectonic interest as much on account of the magnitude and intensity of the crustal deformations, involving the upwarp of the Himalayan chain and the formation at its foot of the deep parallel Indo-Gangetic depressions, as on account of the extreme youth of these world-transforming events.

The region of Northern India resolves itself tectonically into two broad belts, the plicated geosyncline of the Himalayas, and the edge of the Indian peninsular massif, that has acted as the foreland, and in the process sagged under the strain of the folding of the northern orogen. The structure of this foreland is revealed in four principal units: (1) The Rajputana plateau, prolonged northwards into the 'Punjab wedge' of Gondwanaland, which has played such an important part in moulding the trend of north-west Himalaya; its main tectonic strike is transverse to the Himalayan strike. (2) The Potwar trough, a tertiary geosyncline containing 25,000 ft. of fluviatile deposits. (3) To the south-east the Potwar geosyncline widens into the great synclinorium of the Gangetic trough, 1200 miles long and 200 miles wide, mostly filled up by late Pleistocene alluviation. (4) The Assam plateau, a tongue of the Gondwana mainland, has played the same part as the Punjab wedge in moulding the Himalayan trend at its eastern extremity. The Assam valley is a 'ramp' valley.

Few parts of the Himalayas have so far been investigated in detail for their structural plan. Areas in which detailed mapping and stratigraphic and tectonic work have been carried out are the Kashmir mountains, the Simla area, a part of Garhwal, and the neighbourhood of Mt. Everest, in Sikkim. In Kashmir the Himalayan system of earth-folds undergoes a deep syntaxial bend round a pivotal point—a narrow promontory of the Punjab foreland hidden under the late Tertiary deposits. The most important tectonic feature of this north-west Himalaya re-entrant are two concurrent thrust-planes delimiting the autochthonous fold-belt at the south foot of the Himalayas against the edge of the foreland, which have been traced around the syntaxis for a distance of 250 miles. The inner of these thrusts marks the front of the Kashmir *nappe* of pre-Cambrian and older Palæozoic rocks, which has moved southwards along a low plane of thrust and encroached upon the autochthonous belt of Carboniferous-Eocene succession, obliterating it at places. Four overthrusts have been noted in the Simla mountains, representing flat, recumbent folds of great amplitude. The Pre-Cambrian here is piled up on the Carboniferous and Permian sequence. The Simla rocks are totally unfossiliferous and the evidence of the superposition of highly metamorphosed pre-Cambrian, building some of the prominent peaks near Simla (*Klippen*) over the less altered younger rocks, is obtained by a study of relative metamorphism, unconformities, thrusts, etc. In the Garhwal area recent mapping has proved two superposed *nappes*, the Krol and Garhwal *nappes*, composed of the older rock-formations overriding the autochthonous Carboniferous-Eocene sequence of the Outer Himalayas.

Evidence of the extreme youth of Himalayan orogeny has multiplied in recent years; investigations in the Pleistocene, glacial and fluviatile deposits of the Kashmir valley suggest that some 5,000–8,000 ft. of uplift has taken place since the end of the Pliocene. A part of the address dealt with the recently discovered gravity anomalies, both positive and negative, in the Himalayan region, which cannot be explained on the hypothesis of isostasy. On the whole, compensation is in excess in the central Himalayan ranges, while the outer Himalaya is an area of overload and under-compensation.

The arcuate form of the Himalayas, presenting to the south three prominent festoons, is best explained as the result of three crustal pegs arresting the free movement of the plastic folds pressing against the Indian horst under pressures from the north. The Great Himalayan range, built mostly of granite or pre-Cambrian sediments, from the Brahmaputra gorge to Nanga Parbat on the Indus, thus denotes the Himalayan protaxis, the axis of original upwarp of the Tethyan geosyncline. At both its ends it has undergone sharp southward deflections to accommodate itself to the shape of the foreland.

[*To be continued.*]

Research on Crustacea from the "Discovery" Expedition*

VOL. 14 of the "Discovery" Reports is devoted to Crustacea and includes important memoirs on *Euphausia superba*, on the southern species of the genus *Euphausia*, and on Decapod larvæ. The whale krill *Euphausia superba* may be said to be the key animal of antarctic plankton. Its importance as whale food and its enormous abundance make it an ideal subject for research, and the authors of the respective monographs have utilized their unique opportunities to the best advantage. We now definitely know a considerable amount about the development, larval distribution and breeding of one species, the knowledge being based on the examination of a huge number of specimens. There is more to come, for at least another memoir is in progress which will deal with development and distribution of the adult animal. No member of the group has ever been studied so thoroughly as *Euphausia superba*, and the thorough study of this one species will serve as a basis for all future research.

Dr. Gurney's work on the Hippolytidæ is illuminating in many ways, and it is significant that, in this one family of the Caridea where nine larval stages are frequently present and not known to be exceeded, he should refer to both Fraser's and John's present accounts of the development of the Euphausidæ, noting that they find three *Calyptopis* stages and six (or rarely seven) *Furcilia* stages (the term *Furcilia* being used to include all stages between *Calyptopis* and post-larval). Now if we accept the interpreting of stages 1–3 of Caridea as equivalent to the *Protozœa* of Penæidea and the *Calyptopis* of Euphausidæ, as suggested by Gurney in 1926, the total number of possible stages in Caridea is precisely the same as it is in Euphausidæ—a fact certainly in favour of the placing of the Euphausidæ among the Decapods.

---

* Discovery Reports. Issued by the Discovery Committee, Colonial Office, London, on behalf of the Government of the Dependencies of the Falkland Islands. Title Page and List of Contents: On the Development and Distribution of the Young Stages of Krill (*Euphausia superba*) (published December 7, 1936) by F. C Fraser. The Southern Species of the Genus Euphausia (published December 14, 1936) by D. Dilwyn John: The Reproductive System of *Euphausia superba* (published June 25, 1937) by Helene E. Bargmann: Larvæ of Decapod Crustacea. Part 4. Hippolytidæ (published June 25, 1937) by Robert Gurney. Vol. 14. (Cambridge: University Press, 1937).

Fraser has established the principle that there are certain important essential *Furcilia* stages, recognized by the number and state of development of the pleopods, and that these stages predominate to such an extent that one must regard any intermediate stages as unessential and as occurring only occasionally. He also shows that breeding takes place in the deep water, and all early stages are found in the deep water of the far south; *Calyptopis* and early *Furcilias* in warm deep water and in the intermediate vicinity of antarctic surface water, but that the last *Furcilias* and adolescents are always found at the surface and at the ice edge. Adolescents remain at the surface but early stages have a well-defined diurnal migration. Miss Bargmann in her account of the reproductive organs of *E. superba* states that it is probable that the process of egg-laying takes place at a depth of 200 metres or more. She has dissected and examined more than 5,000 specimens in order to determine the state of development of the sexual organs. John describes the adult characters of ten species of *Euphausia*, including *Euphausia superba*, and the development of five others, with their distribution, which is exceedingly interesting; the genus in the cold southern waters consists of two groups of species, one reaching to the far south and each of the four species concerned occupying one of four successive zones of water from north to south, the other, which includes *Euphausia superba*, being circumpolar in range and not so successful in breeding and colonization.

Dr. Gurney is describing group by group the very large collection of decapod larvæ obtained by the *Discovery*. This is the fourth part and in it he has included certain members of the Hippolytidæ from the collection of the Great Barrier Reef Expedition and from his own collections from Gardaqa in the Red Sea. In so doing he has made a very valuable contribution to our knowledge of the larvæ of this difficult family, the larvæ of which are extremely varied and interesting. Besides describing much new material, he has summarized the larval characters in eight genera, and amongst other things has established the fact that Bate's peculiar larval genus *Eretmocaris* is a composite one, made up of a group of forms, probably mostly, but not all, belonging to the hippolytid genus *Lysmata* or some near relative. In thus summarizing our knowledge of the Hippolytidæ, Dr. Gurney shows how much more there is to be done and indicates the essential gaps which should be filled in order to understand the natural relationships of those larvæ.

Irrigation in Egypt

THE Irrigation Services of Lower Egypt, Upper Egypt and the Sudan are the subject of Part II of the annual report of the Egyptian Ministry of Public Works for the year 1929–30, which has only lately been issued (Cairo: The Government Press. P.T. 100). The control and distribution of the Nile waters according to the requirements and crops of the cultivated lands, and the safeguarding of the country from the possible dangers and losses of flooding are regarded as the first and principal duty of the Ministry. In broad terms, this consists in regulating the periodic variations in the river flow to meet the seasonal needs of the agriculturists and in adjusting the authorized croppage to the supplies of water likely to be available. To ensure that an adequate proportion of the plentiful flood waters is retained in storage in order to make up for the natural deficiency during summer, forecasts of the expected state of the river at all seasons are made from time to time, and on these forecasts programmes of distribution are made and progressively adapted as the situation defines itself more clearly. On these and the reports of conditions the Ministry also prepares and executes schemes for the improvement of the system and for the development of cultivable areas to provide for the steadily increasing population.

In the year under review, early forecasts made it necessary, in the first instance, to allot all the supply to the cotton crop, but later forecasts made in April resulted in a modification whereby it was possible, ultimately, to authorize the cultivation of rice areas to the extent of 400,000 feddan. In this year also, the forecasts indicated that the flood would be dangerously high, whereupon the necessary steps were taken to cope with this threat and to carry out such measures of defence and protection as were necessary. In the result, the flood passed safely and without serious accidents or cuts in the banks.

The report is very largely concerned with the day-to-day routine of records of flood, supply, distribution, discharges, allowances, etc., in each of the many areas into which the whole system is divided, and much of this work is illustrated by charts and diagrams. There are also particulars of the buildings, additions, repairs and other constructional and maintenance work undertaken to preserve and extend the facilities and advantages of this vital undertaking.

Closely connected with the work of irrigation in some of its services is the Physical Department, which also comes under the Ministry of Public Works and the report of which is included in this volume. It includes meteorological, hydrological and weights and measures services and a scientific instrument workshop where surveying and other measuring and scientific instruments are repaired, adjusted and calibrated.

The Meteorological Service in 1929–30 with 78 stations, and the Hydrological Service with 345 rainfall stations were very fully occupied in connexion with the needs of the irrigation system, and the report emphasizes the necessity for their enlargement not only in size but also in the scope and development of their work, particularly in research. "New work and new ideas are the life of a scientific department." The growing demand of aviation urges expansion of the meteorological service and the value of instituting research in relation to agriculture and to the climatic causes of the Nile flood are quoted as immediate strong reasons for putting into effect the plans for the extension of its work. Nevertheless, a certain amount of research work is being carried on, including investigations of evaporation at Lake Qaroun and at Gebel Zeraf, and of swamp growths and silting at Aswân, Wadi Halfa and Khaunaq. It is unfortunate that these reports are not available until so long after the period to which they refer.

University Events

EDINBURGH.—The University has awarded the Dewar research fellowship to Dr. C. A. Beevers, lecturer in physics at University College, Hull, for three years from April 1. This is the first award of the fellowship, which was recently established under a bequest of Lady Dewar, widow of Sir James Dewar, for research in physics and chemistry, and on this occasion it has been given for research in crystallography.

OXFORD.—W. H. Cashmore, J. S. Wilson, R. K. Macdowall, and W. J. West have been appointed research officers by the Committee for Rural Economy.

In Congregation on February 8 the University Chest was authorized to set aside out of the Nuffield Trust funds a sum not exceeding £99,944 for the erection and equipment of a laboratory of physical chemistry.

A grant was also made towards the expenses of the University Expeditions of this year to the Cayman Islands and to Greenland.

Science News a Century Ago

Meteorology in America

AT a meeting of the Ashmolean Society at Oxford on February 12, 1838, a letter from Prof. Daubeny, dated at Philadelphia, was read. The letter contained a survey of the state of meteorological science in America and in it Daubeny stated that regular observations were made at Montreal by Mr. M'Cord, who had spared no expense in obtaining the best instruments, and that Mr. Webster, of Albany, from a table of mean temperatures of fifty-three places in the State of New York, had found the highest mean temperature in that State to be 51° and the lowest 43° F. Mr. Redfield, of New York, had advanced a theory that the prevailing storms on the Atlantic coasts have the same character as tornadoes and had prepared a chart to illustrate his views. The phenomena of these storms were explained by Mr. Espy, of Philadelphia, not by a gyratory motion, but by an upward current, which rushes in from all points of the compass towards a central point, where there is a rapid rise of the superficial strata of air into the higher regions of the atmosphere. Mr. Espy's views were stated at length and the letter also contained Daubeny's objections to them. The State of Pennsylvania, it was added, had allotted 4,000 dollars towards instruments for meteorological observations.

James Pollard Espy, who was born on May 9, 1786, and died on January 24, 1860, published his "Philosophy of Storms" in 1841. In 1843 he was appointed to the Washington Observatory, and while there he laid the foundation of the U.S. Weather Bureau.

A Letter from von Humboldt

ON February 12, 1838, at a meeting of the Royal Geographical Society, a letter from Alexander von Humboldt, dated Berlin, January 10, 1838, was read. In the course of the letter, von Humboldt referred to Schmoburgk's travels in Guiana, the work of M. Federoff who had spent five years in northern Asia, the trigonometrial survey between the Black Sea and the Caspian Sea, and to the subject of magnetic observations. Of the observations being made at Berlin, he said, "As we make observations here, both with the needle of Gambey, furnished with microscopes, and with the new apparatus of Gauss, furnished with a mirror, we have an opportunity of convincing ourselves more and more of the greater perfection of the latter apparatus, which by degrees will be employed in all our great observatories.

"As I think that the subject is not without importance to seamen, I beg you to invite the influential members of your Society to be good enough to propagate Gauss's manner of observing in all new stations where intelligent people can be found. Points near the magnetic equator and those which are in high latitudes in the southern hemisphere . . . would be most desirable if they would observe at the same epochs indicated by M. Gauss."

Richard Owen receives the Wollaston Medal

AT the anniversary meeting of the Geological Society held on February 16, 1838, at which Darwin was elected one of the secretaries, the president, the Rev. W. Whewell, in presenting the Wollaston Medal to Richard Owen, said: "Mr. Owen,—I have peculiar pleasure in presenting to you this medal, awarded to you by this Society, for your services to Fossil Zoology in general, and in particular for the description of the fossil mammalia collected by Mr. Darwin. I trust it will be a satisfaction to you to receive this our testimony of the success with which you have cultivated that great science of comparative zoology, to which you have devoted your powers. I trust it will add to your satisfaction, to consider that the subject which we more particularly wish to mark on this occasion—the Study of Fossil Zoology—is one to which the resources of your new science were applied, while the subject was yet new, by that great man—John Hunter—whose museum and whose reputation are so worthily consigned to your care. . . ."

Milne-Edwards on Annelidæ

"M. Milne-Edwards", said the *Athenæum* of February 17, 1838, "has been making some interesting and important observations on the circulating apparatus of the Annelidæ, which has been but little studied, excepting in the leech and earthworm. He finds a great diversity among the different genera. For instance in the Terebellæ, the branchiæ act as an arterial heart and organ of respiration. Among the Arenicolæ, the vascular tufts on the back equally fulfil the double functions of heart and branchiæ and there are besides two ventricles, which by their pulsations, send the blood into the dorsal vessel. In the Eunice, the course of the blood is determined by the contraction of a series of vesicles, situated on each side of the ventral vessel, and sending out canals which go to the branchiæ. These vessels are consequently little pulmonary hearts; and as a pair of them exists in almost all the rings of the body, these singular Annelidæ often possess hundreds of hearts."

Henri Milne-Edwards (1800–1885) was elected to the Paris Academy of Sciences in 1838 and afterwards filled the chairs of entomology, zoology and physiology at the Jardin des Plantes.

S. N. Jagužinskij: Structure of species of protococcous algæ, *Scenedesmus* Meyen.

Tokyo

Imperial Academy (*Proc.*, 13, No. 9; 1937).

Obituary notice of Prof. Toyokichi Takamatsu, known for his work in chemical industry in Japan.

Masao Sugawara: The transformation theory of Siegel's modular group of the *n*th degree.

Yukiyosi Kawada: Remarks on M. Moriya's construction of the classes of group theories of algebraic functions.

Takeshi Inagaki: The classes of constituents of complementary analytical groups.

Tokui Satô: The differential equation $y'' = f(x, y, y')$.

Masao Inouye: A consideration of the problem of Dirichlet.

Tokio Takéuchi and Takanosuke Sugita: A method of producing a photographic image of a dark hot body in darkness. The method adopted involves the quenching of phosphorescence by infra-red light.

Shinkichi Yashimura: Limnology of two lakes on the oceanic island, Kita-Daitô-zima.

Masuzô Ueno: Plankton of the lakes in Kita-Daitô-zima.

Tokio Shikama: Ossiferous fissure deposits of Kuzuii Totigi Prefecture.

Kiyoshi Takewaki: (1) Fate of the zona reticularis in the adrenal cortex of castrated male mice. In certain circumstances, the zona reticularis remains for a year and a half (sometimes longer) after castration; but various types of degenerative phenomena occur in the zone of males which have long been castrated. (2) Postponement of appearance of œstrus following interruption of pregnancy in lactating mice. Lactation inhibits for some time the advent of œstrus following the removal of the uterus containing fœtuses.

Takeo Kamada and Haruo Kinosita: Graded response of the muscle of the Japanese giant crab to indirect stimulation.

Yositiro Umeya: Preliminary note on experiments of ooplasm transfusion of silkworm eggs, with special reference to the embryo. Whether or not the development of the embryo in the wintering egg will begin depends upon the solubility of the yolk, and the phenomenon of egg-wintering is shown to be based primarily on the ooplasm and not on the embryo.

Forthcoming Events

Monday, February 14

Royal College of Surgeons of England, at 5.—Sir Arthur Keith, F.R.S.: "The Prehistoric People of Mount Carmel".

Royal Geographical Society, at 5.—J. Hanson-Lowe: "The Structure of the Lower Yangtze Terraces".

Wednesday, February 16

Royal College of Surgeons of England, at 5.—Dr. W. E. Gye: "Some Recent Work on Experimental Cancer Research"

Thursday, February 17

Chemical Society, at 8.—Prof. A. Findlay: Franklin Memorial Lecture.

Friday, February 18

Institution of Chemical Engineers (at the Hotel Victoria, Northumberland Avenue, London, W.C.2).—Annual Corporate Meeting.

Dr. William Cullen: "A Milestone" (Presidential Address).

Royal Institution, at 9.—Prof. E. N. da C. Andrade, F.R.S.: "Science in the Seventeenth Century".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned

Assistant (grade III) in the Ballistics Directorate and a Junior Scientific Officer in the Radiological Directorate of the Research Department, Woolwich, S.E.18—The Chief Superintendent (February 14).

Lecturer in Mechanical Engineering in the Leeds College of Technology—The Director of Education, Education Department, Calverley Street, Leeds 1 (February 16).

Junior Scientific Officer at the Air Defence Experimental Establishment, Biggin Hill, Kent—The Superintendent (February 18).

Assistants (grades II and III—refs. 6070 and 6270) at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (February 19).

Lecturer (woman) in Geography in the Goldsmiths' College, New Cross, S.E. 14—The Warden (February 28)

Assistant Government Analysts in the Straits Settlements—The Director of Recruitment (Colonial Service) 8 Buckingham Gate, London, S.W.1 (March 21)

Two Demonstrators in Physiology in the University of Liverpool—The Registrar (April 1).

Overcrowded Professions

AN 'unemployment' problem which has for years baffled university and State authorities in many countries and has, in some, assumed an aspect of tragic intensity for the individuals immediately concerned and of menace for the community, is dealt with by Prof. W. M. Kotschnig in a valuable survey of the subject recently published*. It is scarcely too much to say that the magnitude of the problem is not yet fully appreciated. Here, in Great Britain, where unemployment of university graduates has been on a relatively small scale, although it has given rise to some anxiety in the case of the teaching profession, it has not been 'in the news', but it has been the subject of intermittent investigation and discussion since 1930, and a series of precautionary and preventive measures were suggested at last year's congress of the National Union of Students. The consideration of any such suggestions will be greatly facilitated by reference to Prof. Kotschnig's lucid account of the conditions of the problem and of solutions attempted in various countries, and his comments, criticisms, and suggestions which are evidently the fruit of close observation and long study. In his "Planless Education", published in 1935, he gave a preliminary report of the results of the world-wide survey of the situation undertaken in 1932 by International Student Service, Geneva, of which he was formerly general secretary. For the present volume, that report has been revised, brought up to date, amplified, and developed.

The main theme—unemployment of university graduates—is introduced by an account of the actual situation in each of twenty-two countries and this is followed by an estimate of causes and effects. The situation is blackest in Austria and Hungary, where the overcrowding of the professions is described as complete and absolute. "In Germany, the 40,000 or 50,000 workless university graduates in 1931–33 became, together with unemployed subalterns of the old Imperial army, the spearhead of the National-Socialist movement." There is, as yet, no other country in the world with such tens of thousands of unemployed graduates, "but there are many countries which are not far from the danger point".

The social problems created by the surplus of university graduates have created "counter-measures", to which Prof. Kotschnig devotes particular attention. A discussion of numerical restriction, the *numerus clausus*, leads on to a consideration of the German law of April 1933, which had the effect of reducing admissions by a half. This drastic limitation of numbers was accompanied by a change in the quality of entrants, due to the introduction of new criteria of selection: race, sex, character, and national reliability (*nationale zuverlassigkeit*), sincerity of outlook (*lauterheit der gesinnung*), bodily prowess, and capacity for comradeship and devotion. This accords with the new conception of the university, introduced with the Nazi regime, as existing for the advancement, not of knowledge in general or of the education of the individual, but of the National-Socialist State. Simultaneously, there was a ruthless elimination from the professions of Jews and others obnoxious on account of their political opinions or affinities. By this rough surgery the urge for higher education (or its diplomas) was checked, and overcrowding relieved.

---

* "Unemployment in the Learned Professions: an International Study of Occupational and Educational Planning." By Prof. Walter M. Kotschnig. Pp. xii+348. (London: Oxford University Press, 1937.) 12*s*. 6*d*. net

Upon the subject of occupational and educational planning Prof. Kotschnig insists, with perhaps exaggerated emphasis, on the irresistible, "almost elemental" strength of the modern urge for education (most of which might, perhaps, be more justly called "urge for diplomas"), as evidenced by statistical tables. The forces manifesting themselves in this urge—craving for a fuller life, desire for the better pay and social standing to which academic qualifications lead, and faith in the power of knowledge—these forces, far from being played out, are, in many countries, gaining momentum as progress is made towards educational emancipation of the "under-privileged". In Germany this historical trend has been arrested. Under the National-Socialist regime, educational planning has there involved drastic restriction of educational opportunities, and a solution of the problem of overcrowded professions has been reached as part and parcel of a reactionary movement which scorns academic freedom, has little use for the ideal of equal educational opportunity, and has resuscitated the warrior ideal—"a nation of soldiers" (Dr. Goebbels). Elsewhere, such a solution will not, in Prof. Kotschnig's opinion, prove acceptable, and it is suggested that a more excellent way—or, rather, ways, for diversity of conditions in different countries forbid the application of a general prescription.

It is especially in the field of secondary education that replanning is indicated. Except in Italy, where, as a result of Gentile's reorganization of 1923, half of the secondary education is now vocational, there has been a wholly inadequate adjustment in this field to changing social needs. It is pointed out that, in communities where the process of mechanization of industry has been most highly developed, the great majority of young people leaving secondary schools must enter occupations which do not call for any prolonged vocational training, but rather for a well-trained mind and adaptability. Hence the ruling aim of the ordinary secondary school in such communities should be "an education broad enough to fit them not only for work, but for an intelligent and creative use of their leisure time, a training enabling them to be active members of an enlightened citizenry". There should be, in addition, schools of two special types for those pupils whose special aptitudes mark them out for a career (1) in the professions, or (2) as highly skilled craftsmen or technicians. It is suggested that such a clarification of aims and differentiation of types of secondary schools should lead to an improvement in quality of their product so great that the social prestige and equipment for life of the secondary school graduate would approximate to those of the ordinary university graduate.

Palæolithic Age in Palestine

The Stone Age of Mount Carmel:
Excavations at the Wady el-Mughara. By D. A. E. Garrod and D. M. A. Bate. (Report of the Joint Expedition of the British School of Archæology in Jerusalem and the American School of Prehistoric Research, 1929–1934.) Vol. 1. Pp. xii + 240 + 55 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 42*s*. net.

THE foreword by G. Grant MacCurdy to the work under notice recalls that, after the discovery of a fragment of Neanderthaloid skull in Galilee (1925), and the International Archæological Congress at Jerusalem (1926), he had the pleasure in 1928 of following the excavations of Miss Garrod at Shukbah, Wady en-Natuf, 27 kilometres north-west of Jerusalem. He mentions Miss Garrod's fine excavations at Gibraltar a short time before, in which she had found a skull of Neanderthal type. Then came her successful expedition to Iraq (1928) and, finally, in 1929, her excavations, for the joint expedition mentioned in the title above, at Wady el-Mughara in the coastal zone near Haifa, where she was ably assisted by T. D. McCown.

No fewer than eighteen societies and institutions, six of which were British, contributed to the considerable expenses of the expedition, and the great quantity of archæological material obtained was distributed amongst forty museums or institutes. In 1932, for reasons of health, Miss Garrod had to hand over the direction of the excavations to Mr. T. D. McCown, who later gave all his time to the preparation of various Neanderthaloid skeletons found just then by him.

The palæontological classification was undertaken by Miss D. Bate, and the study of the anthropological remains still goes on at the Royal College of Surgeons and will be described in future volumes.

The excavations were prosecuted successively in three neighbouring caves, rich in deposits, in the hilly valley on the slopes of Mount Carmel, on the left of the "valley of the caves", Wady el-Mughara, just where it debouches on the coastal plain. Mughara-el-Wad was first excavated, then Mugharet-es-Skhūl and finally Et-Tabūn, in which deposits nearly 20 metres deep exceeded those of both the previous caves. In a series of chapters describing the stratigraphy and archæology of the sites, Miss D. Garrod, and, for Mugharet-es-Skhūl, Mr. McCown, tell of the results obtained. Needless to say that while congratulating the authors on their excellent and sober descriptions, we cannot give a detailed account of these, but pass immediately to their conclusions (chap. viii), where we learn that in the three sites, not counting superficial deposits of Bronze Age or more recent date, there are twelve archæological and palæontological levels graded in exact sequence, which can, if preferred, be reduced to ten. The oldest are found only at et-Tabūn, where the enormous deposits stretch from the Tayacian to the Upper Levalloiso-Mousterian, whilst Mugharet-es-Skhūl was only occupied from the Lower-Lavalloiso-Mousterian, and Mugharet-el-Wad begins in the Upper Levalloiso-Mousterian, but possesses three Aurignacian levels, one Atlitian and two Natufian.

Such an important sequence tells the whole human history of the Palestinian district and also agrees with the partial results obtained by other excavators, such as R. Neuville and M. Stekelis in the Judean desert. It also makes possible a comparative study of former excavations. Still this work does not classify the earlier industries, such as those in the open-air sites, like the Abbevillian of El Beka (Jerusalem) and others which are old Acheulean and primitive Levalloisian in the Beyrouth region. The lowest level contains a flake industry (Tabūn *G*) resembling the French Tayacian in its chipping technique of an oblique striking platform, and its position which underlies the final Acheulean, where there are no associated bones. This is confirmed by the discoveries of R. Neuville at Oum Qatafa.

Above (Tabūn *F* and *E*) there is a very fine Upper and Final Acheulean (Micoquian) already known at ez-Zuttiyeh (Galilee), where it was mixed with the Levalloiso-Mousterian, and at Oum Qatafa, etc. There are always a certain number of flakes with prepared striking platforms, more frequent near the top, and various types of scrapers, gravers with Audi or Châtelperron points, tools appearing at a later date in Europe.

Then the very long Levalloiso-Mousterian cycle begins, divided into levels *D*, *C*, *B*, at Tabūn, *F*2 and *G* at El Wad, *B* and *C* at es-Skhūl with slight morphological variations in this already evolved industry (such as the proportion of points and side-scrapers, the diminution from bottom to top in the number of axes, the presence of gravers and scrapers) all of too technical an interest for this short review, as is their comparison with those in the various excavations of R. Neuville, the ones at Shukba and those made by Zumoffen. In the course of development of this industry, important changes of fauna are noticeable—the disappearance of big pachyderms and the increase of Cervidæ. It was during this period that a tribe of Neanderthaloid men lived in the Wady-el-Mugharet. Of these, Miss Garrod has found one specimen at Tabūn in level *C*, and some fragments.

Mr. McCown found quite a cemetery of Neanderthaloid individuals. His account of their discovery in the narrow space of about 9 × 4 metres, of the measures taken for collecting them and determining their position, and the photographs and drawings which recorded these, form a deeply interesting whole, doing great honour to Miss Garrod's devoted fellow-worker.

At El-Wad, the lower Aurignacian rests on the Upper Levalloiso-Mousterian, with which it is mingled as at Mugharet-el-Emireh, but Neuville found it pure at Jebelqafseh. There are Châtelperron points and another type called El-Emireh, typical of that Palestinian level; it is a triangular point with base reduced by bi-facial trimming. The different types of gravers (angle, polyhedric, beaked, etc) exist, though there are not many; but blunt backed blades are abundant.

Then, towards El-Wad, there are two mid-Aurignacian levels. The yet lower level noted by Neuville at Irq-el-Ahmar and Jebelqafseh, distinguished by the presence of blunt backed points, nose scrapers and beaked gravers, and the absence of El-Emireh and Font-Yves points, is lacking here.

Most of the known Western types of flints are found, but, except that their working improves, especially in level *D*2 of El-Wad, where there are a good many fragments of blades with broad marginal trimming and more nose scrapers than there are lower down, there are fewer gravers, though of the same types—angle, ordinary, polyhedric, beaked, flat, etc. But points of Font-Yves type with a sharp point and nibbled edges are only found in lower levels. No bone industry is mentioned.

Similar industries at Nahr-el-Kelb and Antelias (Beyrouth) have long been known, and Neuville found them at Irq-el-Ahmar and El Khiam.

Level *C* of El-Wad, which follows, Miss Garrod calls Atlitian to avoid the question of connexions with the African industry, instead of Capsian as she first called it; it is also not definitely Upper Aurignacian. What characterizes this level is the great number of Châtelperron points and a mass of polyhedric gravers. For the first time here, we note two pierced shells. At El Khiam there is a related industry.

It only remains for me to discuss the very important Natoufian level crowning the Palæolithic series. A hiatus exists here at its base, filled up at El Kebarah by the special microlithic industry found there by Mr. Turville Petre under the lower Natoufian. This "Kebaran" is distinguished by long narrow microlithic blades, with blunted backs and sharp or obliquely chopped points, associated with small gravers and scrapers. At El Kebarah, the Lower Natoufian was rich in sculptured and worked bones (T. Petre), as in different sites of the Judean desert (R. Neuville). The latter divided the Natoufian into four levels of which I, II and IV are found more or less at El-Wad; IV is the level with notched arrowheads.

At El-Wad, level *B*2 (lower Natoufian) is extraordinarily rich in the geometric types of tool; lunates are distinctive of Helouan (Egypt) with triangles, rather rarer trapezes and a good many micro-gravers. There are blades with chopped ends and blunted backs meant to be hafted in series as sickle-blades, and many kinds of gravers and scrapers, thick rods or 'fabricators', and a kind of pick. Most of these types are also in the Upper Natoufian, but with the notched arrowheads of Helouan forming a link with the Mesolithic of Lower Egypt.

Natoufian bone tools, although less rich than the stock at El-Kebarah (T. Petre), include a good many bone points or awls, polishers, etc.; besides some fragments of very simple harpoons, the most important are sickle-hafted with a deep groove to insert sickle-blades, such as those at Helouan, some of which have been found fixed. A very pretty sculpture of a young deer-like animal was found in 1928 by Mr. Lambert in a sounding and is probably part of a sickle-handle. A second sculpture, a small human head in stone, is very rough.

It is perhaps the dawn of agricultural conditions, which is revealed in the Natoufian by the discovery of pieces of pestles and mortars in basalt and limestone, sometimes coloured with ochre, decorated with moulding, and ending sometimes in an animal's hoof. Still more remarkable is the terrace, suggestive of a place of primitive worship, quite clearly lower Natoufian in date, with a quantity of deeply hollowed basins on a ledge 1·5 metres × 2 metres, encircled with a rim, surrounded by remains of a flat stone kerb, and near a dry stone wall 8·5 metres long, the lower half made of single blocks 0·50–0·70 metre in diameter. This place, probably used for religious ceremonies, was also the centre of a great number of burials (forty); fourteen were in perfect preservation. Another group in the centre of the first room showed three layers of bodies, one on the other, stretched out and lying on their backs (ten in all). Those on the terrace differed by being flexed. Five of them had very elaborate personal ornaments, illustrated here by splendid photographs, crowns made of dentalium, cleverly arranged lengthwise, cross-wise and in fan-shapes. They had necklaces too, made of dentalium, alternating with 'twin' pendants, which seem to me to imitate the canines of deer, with distal segments cut from gazelle phalanges, or from the tarsian tibia of birds, sometimes notched.

I suppose the skeletons and their very remarkable personal decorations will be more extensively discussed, when the time comes for the detailed description of the bones.

The second part of the volume is devoted to the study, by Miss Bate, of the fauna; in spite of its great merit, it is too technical to be discussed at length. We must confine ourselves to confirming what this distinguished palæontologist says, namely, that the Upper Acheulean *F* level contains a good many extinct species, suggesting damp tropical conditions. Dry conditions prevail in Acheulean *E* and lower Levalloisian *D*, where *Hippopotamus* and *Rhinoceros hemitechus* are still found.

The rainy phase occurs at the end of *C* (mid-Levalloiso-Mousterian) in which the number of big bovines increase greatly. In *B* (Upper Levalloiso-Mousterian) we reach an extremely wet but not very warm phase, producing a very marked change of fauna, the big pachyderms definitely disappearing. During the Aurignacian, the climate grew warmer, but became—except for a slight increase in humidity in the middle—drier and drier until the end of the Natoufian; gazelles increase as the deer diminish. In the Natoufian, the domestic dog appears.

L. Picard considers that a minor damp period should be inserted just before the Bronze Age. In spite of the temptation felt to correlate the succession of wet and dry periods with the Western glacial stages of Riss and Würm, which seems to me fairly likely, Miss Garrod awaits discoveries in open-air sites, and especially those near the coast, before announcing her opinion.

Such are, much abbreviated, the fine results obtained by Miss D. Garrod and her fellow-workers during their six years work at Wady el-Mugharet. Thanks to her, and to the allied excavations of R. Neuville, Turville Petre, etc., the Palæolithic stage in the Palestinian caves is one of the best known in the world to-day, and for this we congratulate her.

H. BREUIL.

Science and Philosophy

Philosophy and the Physicists
By Prof. L. Susan Stebbing. Pp. xvi + 295. (London: Methuen & Co., Ltd., 1937.) 7*s.* 6*d.* net.

THE relations between science and philosophy have assumed a new aspect in this generation. The remarkable developments of physics, which have called for a reconsideration of certain fundamental concepts, have made it, if not impossible, at least highly undesirable, for these two departments of thought to maintain the attitude of superior indifference with which labourers in each have sought to conceal their incapacity for the work of the other. The physicist, if he is to avoid the slough of metaphysics which lies close to his new scene of operations, must learn to recognize its characteristics; and the philosopher, seeing his categories overrun by barbarians, is forced to fight the invaders with their own weapons, in the use of which he is unskilled. An interesting situation is thus created, which, it is to be hoped, will develop into better understanding and more friendly relations.

If we have succeeded in what may be the impossible task of taking an impartial view of the matter, we may say that the most essential fact is that modern physics has something vital to say to philosophy. It has brought to light principles of general philosophical import, by means of which a vast amount of apparently unrelated experience has been fused into a connected rational system with the power of extensive, if not unlimited, growth. Whatever their shortcomings may be, those physicists who have tried to interpret the new work in philosophical terms are aware of this. They behold the light, even if they are somewhat confused about whence it flows, and the vision splendid is to be seen by those who read between their lines. There is little evidence, however, that philosophers in general have caught a glimpse of it. The only philosophy (except, perhaps, that of Prof. Whitehead, which bears a relation to modern science that is still somewhat obscure) which takes explicit account of the principles animating modern physics seems to be logical positivism, which, in spite of certain merits, is a sorry enough creed. A few years ago, Mr. C. E. M. Joad published a book entitled "Philosophical Aspects of Modern Science" which, so far as it bore any relation to modern science, was concerned only with the unphilosophical aspects of modern physicists. Even Prof. Stebbing, fairest of critics, misses this primary fact of the situation. How otherwise can we account for the sweeping statement on p. 283—"Every scientist turned philosopher tends to find support in his special studies for the metaphysical theory which *on other grounds* he finds attractive"—when only four pages earlier she has said of her chief victim, "It is indeed clear that this is the change [the change in the status assigned to physical laws] that gave to Eddington's conception of the physical world that 'idealistic tinge' which was entirely different from the complexion of his earlier philosophical views"?

On the other hand, the philosopher may justly claim that physicists should present their findings in language which he can understand. It is unfair to expect him to become a physicist or to exchange logical habits of thought for cheap emotionalism. If the physicist claims to have found something important for philosophy and wishes philosophers to understand it, he should enter their courts as a guest, and honour the obligations appertaining to that dignity. Though he may not be prepared to make philosophy his pattern, he should be willing to live for a while in her mild and magnificent eye and learn her great language. It cannot be denied that physicists are not above reproach in this matter. When Sir James Jeans, for example, claims that on fundamental problems science must speak before philosophy, and assumes the role of spokesman with the comment that although not a philosopher either by training or by inclination, he has the better view of the game proverbially granted to the onlooker, he invites Prof. Stebbing's acid retort that the proverb applies only to those who know the rules observed by the players. There is certainly room for a better appreciation of philosophical problems, and a wider knowledge of the attempts already made to solve them, on the part of those physicists who cry the merits of their own particular nostrums.

It is this right of the philosopher (or, rather, of "the common reader", for it is as such that she somewhat too modestly claims to speak) that Prof. Stebbing asserts, and she supports her case by subjecting the works of Sir James Jeans and Sir Arthur Eddington to a minute analysis. Other writers receive occasional attention, and there is some independent discussion of abstract problems, but it is clear that Jeans and Eddington are "the physicists" and that the main purpose of the book is to show how far they are from being philosophers and how far removed from intelligibility are their writings. Jeans's work is too crowded with inconsistencies for any clear idea to emerge, and

Eddington not only is so anxious to write pure poetry that he forgets that some of his readers would like to know what he means, but also is so fascinated by the products of his imagination as to be unable to form a consistent philosophy for himself. These theses Prof. Stebbing seeks to establish in terms which, with respect to both purport and temper, are unexceptionable. She is severe but never spiteful, and she has the faculty of expressing cardinal points in a sentence. For example—"Jeans makes no effort to explain how it is that the Great Mathematician should have turned aside from his mathematical activities and condescended to create the world" ; and again—"The problem that confronts Eddington is to get as much uncertainty, or 'indeterminacy', as he can out of the miserably small amount represented by Planck's constant."

How far Prof. Stebbing establishes her case the reader must be left to judge. Two tempting but superficial criticisms may, however, be forestalled. The first is that in dissecting Eddington's parables and allegories she is revealing insensitivity to their character and producing something equivalent to a logical analysis of one of Blake's lyrics. This would be a fair criticism if the process were not necessitated by Eddington's own method. The attempt to find the flaw in his more closely reasoned passages leads inevitably to an idea first introduced playfully in an anecdote and thereafter treated as though it had been logically established. Consequently there is no alternative to breaking the butterfly on the wheel.

The second criticism that might be made is that the book is too much occupied with the splitting of hairs. It is true that some fine distinctions are made, though most of the 'hairs', alas, are only too rope-like. Hair-splitting, however, is a process quite properly indulged in by specialists in every field, and it appears pedantic only when practised by others. Physicists are more expert at the process than most. It was hair-splitting that discovered the noble gases, and no philosopher has yet split a hair so fine as that severed by the statement that the law of gravitation is not precisely that of the inverse square, yet the resulting strand has to bear the weight of all modern theories of the universe. When the fundamental problems of human existence are in question, therefore, it can scarcely be held superfluous to isolate the less than a hair that perchance divides the false and true.

The problems aroused by the book have more than academic importance. We have been told, for example, that more than 100,000 copies of "The Mysterious Universe" have been sold. The number that have been understood is precisely nil, if, as Prof. Stebbing suggests, the book is essentially unintelligible. What process, then, went on in the minds of many readers to produce an illusion of understanding and lead to the dissemination of its phrases from pulpit, press and platform ? The implications of that question call for serious consideration by those interested in the future of democracy.

H. D.

The Science of Radio Engineering

Radio Engineering

By Prof. Frederick Emmons Terman. Pp. xiii + 813. (New York and London : McGraw-Hill Book Co., Inc., 1937.) 30*s*.

A CERTAIN ruthlessness is inevitable in any text-book, and the permissible coefficient of ruthlessness is higher in engineering than in physics. Yet there is room for doubt whether a book on radio engineering which does not once mention the names of such founders as Clerk Maxwell, Popoff, Marconi, Jackson, Oliver Lodge, Larmor and Eccles does not fall below that level of piety which may fairly be demanded of even the 'toughest guy' in applied science. It is also to be doubted whether a book in which the first chapter, on the "Elements of a System of Radio Communication", is so ruthlessly shorn of qualifications, limitations and explicit cautions about implicit assumptions and simplifications is safe reading, even for engineers. The spiritual danger is obvious, but that there is much practical danger is well illustrated in such things as the misapplication of the "Rayleigh-Carson reciprocal theorem", a sharp-edged tool which is of great value in sufficiently subtle hands, but which produces strange shapes from the hand of the ruthless.

Despite such blemishes, the first edition of Terman's "Radio Engineering" established itself, rightly, in the first rank of guides to the transformation of radio engineering from an empirical and only roughly quantitative art into a logical and closely calculated science. The second edition, almost wholly re-written and very generously illustrated, will be of still greater value and will be welcomed by the great army of industrious 'Termanites' on both sides of the Atlantic—and of the Pacific.

, as the author's preface points out, o two parts. The first, dealing in 500 pages with fundamental properties, has chapters on circuit constants, properties of resonant circuits, vacuum tubes, vacuum-tube amplifiers, power amplifiers, vacuum-tube oscillators, modulation, vacuum-tube detectors and sources of power for operating vacuum tubes. The second part, devoting nearly 300 pages to more specialized radio topics, covers radio transmitters, radio receivers, propagation of waves, antennæ, radio aids to navigation, television, sound and sound equipment. It is far from adverse criticism to say that the whole forms a connected and reasoned guide to the last ten years' issues (up to a remarkably recent date) of the *Proceedings of the Institute of Radio Engineers*, to which the reader is, in copious and well-chosen footnotes, referred for fuller information. That air of intellectual nationalism which results from the natural tendency of an American teacher to refer American students mainly to American books and periodicals is not very offensively marked for the British reader, but the German, French and Dutch contributions to radio engineering are severely attenuated by the band-pass filter of an assumed unilingualism.

The first part of the book, on circuits and their components, is clearly the author's own territory, and is extremely good and comprehensive, with considerable tracts of original work which will be valuable to all radio engineers. The second part, and particularly the chapters on propagation of waves and on radio aids to navigation, are much less satisfactory, mainly because the light and shade of these subjects lend themselves badly to that sharp black and white treatment which so notably smooths the student's way through circuit work.

Prof. Terman's second edition will enhance the high reputation gained by his first, and should be at the right hand of every radio engineer. His half-tone blockmaker has invariably, and his line draughtsman not infrequently, served him ill, but the book is otherwise very pleasant to handle.

A New Guide to the Organic Molecular World

Dictionary of Organic Compounds: the Constitution and Physical and Chemical Properties of the Principal Carbon Compounds and their Derivatives, together with the Relevant Literature References. Edited by Prof. I. M. Heilbron and H. M. Bunbury. Vol. 3: Naphthacarbazole—Zygadenine. Pp. xii+943. (London: Eyre and Spottiswoode (Publishers) Ltd., 1937). £6 6*s*. net.

THE appearance of this volume completes the production of the first dictionary of organic compounds in the English language. The high standard of the first two volumes (NATURE, 134, 751, Nov. 17, 1934; 137, 342, Feb. 29, 1936) has been maintained, and the whole work has been published within a period of three years. This is a truly remarkable achievement, in which all concerned may take a pardonable pride. More than that, the publication of such a work by a team of British chemists speaks volumes for the wonderful progress which organic chemistry and biochemistry have made in Great Britain during the past twenty years.

Only those whose duties call for daily references to the vast and complicated literature of organic chemistry can realize to the full the great service which Prof. Heilbron and his collaborators have rendered to the *Fachgenossen*. Here is a work of some 2500 pages, printed in beautifully clear type, occupying less than 7½ inches of shelf-space, self-indexing, and affording thoroughly up-to-date information concerning the great majority of important organic compounds: a magic casement looking out upon that boundless organic molecular world "whose margin fades for ever and for ever when we move".

Even the unremitting expansion of this organic universe is to be followed, although not (we are glad to notice) by the issue of an indefinite succession of supplementary volumes. The editors propose to adopt a more practical and time-saving method for keeping a work of this nature up to date, by issuing revised volumes at regular intervals, beginning probably in 1939. Thus the three-volume format will be a recurring characteristic of the "Dictionary", which will also, of course, remain as a self-indexing entity.

Prof. Heilbron, Mr. Bunbury, their growing team of skilful and enthusiastic collaborators, and their publishers, deserve the thanks of all workers in organic chemistry and biochemistry for this elegant agent, which will catalyse so effectively the future labours of the fraternity.

JOHN READ.

Genetics and the Origin of Species

By Prof. Theodosius Dobzhansky. (Columbia Biological Series, No. 11.) Pp. xvi + 364. (New York: Columbia University Press; London: Oxford University Press, 1937.) 18*s*. net.

THIS well-designed and lucidly written book by one of the foremost younger geneticists is a thoughtful contribution to the problem of the origin of species. Not only does the author bring forward a clear and balanced statement of the genetical viewpoint, but he also supplies an exposition of recent genetical, cytological and statistical work in a form which is easily assimilated by the non-specialist.

The author divides his subject into (1) changes in the individual, (2) changes in the population, (3) fixation of these changes. Under the first heading are discussed gene and chromosome mutations, and the relation between evidence from the laboratory and that found in the wild. Under the second, a lucid description of the work of Wright, Fisher and Haldane leads to an estimation of the relative importance of selection, population size and variability in evolution. Under fixation of changes the author gives an extended account of polyploidy, hybrid sterility and other forms of isolation. The concluding chapter contains several pertinent remarks on the status of species.

The reassessment of old theories in the light of the experimental evidence is performed with a caution and soundness which will repel only those who are dogmatic upholders of tradition.

This is probably the best recent book for students who have an elementary knowledge of Mendelism, mitosis and meiosis, and who desire to understand the genetical evidence and viewpoints in biological questions. F. W. S.

Appendix to the Four Volumes of the "Mysore Tribes and Castes" (Index and Bibliography)

By Diwan Bahadur Dr. L. K. Ananthakrishna Iyer. Pp. iv + 70. (Mysore: Mysore University, 1936.)

AN ethnographical gazetteer loses half its value if it lacks an index; but the appendix which the late Dr. Ananthakrishna Iyer had added to the four volumes of his "Mysore Tribes and Castes" makes an even more generous provision for the needs of the student. In addition to index and bibliography, his supplementary volume includes a glossary of vernacular terms, and lists of endogamous groups and exogamous clans. Attention is directed to the evidence to be found in these lists of the tendency of endogamous groups to increase, notwithstanding attempts made to bring about union, and the disappearance of totems in favour of gotras of Puranic heroes.

The bibliography would be of much value to students if it were not for numerous errors and omissions of detail due to insufficient preparation and indifferent proof-reading, for which Dr. Ananthakrishna Iyer, who died in February 1937, is probably not responsible. As it stands, it is of little use to anyone who cannot identify many of the references from previous knowledge of anthropological literature.

Manual on Research and Reports: a Guidebook of Procedures helpful in [illegible] Investigations and presenting Reports on Su[illegible] the Fields of the Social Sciences.

By the Committee on Research of the Amos Tuck School of Administration and Finance, Dartmouth College. Pp. x + 140. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 7*s*. 6*d*.

THE steady stream of complaints, of which that by Dr. G. W. C. Kaye in his presidential address to Section A at the British Association meeting in Nottingham is only one of the most recent, regarding the deficiency of science graduates in writing reports and the ability to express themselves in concise and lucid English, has already called forth a number of books intended to correct this defect.

The present manual forms an admirable addition to this literature. It is concise and well written, and although designed primarily for those concerned with economic or social research, the chapters on preparing the manuscript and the anatomy of a report, as well as on guarding against error, and submission to a printer or publisher, can be read with profit by most scientific workers, whether engaged in academic or in industrial research. Many of the points may be seen to be matters largely of common sense, but experience suggests that the careful and thoughtful reading of the chapters on the collection of first-hand information, recording and organizing information, analysis and interpretation of data will well repay most recruits to scientific and industrial research.

Useful, however, as this manual is likely to prove, it is little credit to our educational system that such literature as this should still be meeting a definite need.

Einführung in die Physik

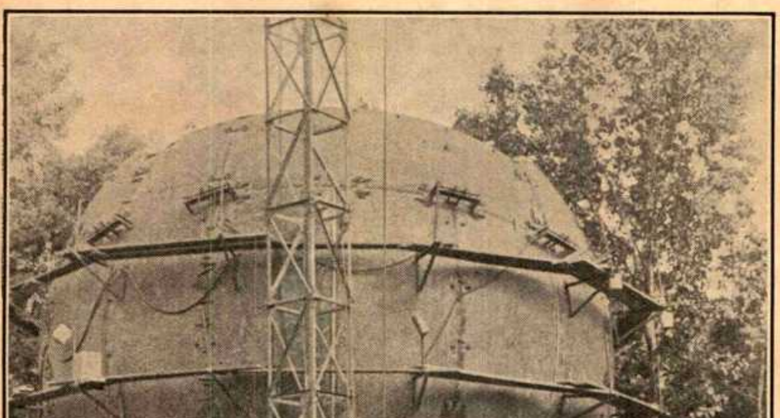
Von Dr. Otto Blüh. Pp. xvi + 582. (Berlin: Gebrüder Borntraeger, 1937.) 16 gold marks.

DR. BLUH has written an introduction to physical science which is a valuable contribution to the literature of the subject. His book represents roughly that part of the content of physics which may be assumed to be the property of a well-prepared student for a general honours degree or of a student revising the preliminary stages of his reading for special honours. No topics of serious importance are omitted and the main thesis is developed logically and clearly through some 500 pages, from the first section on "Masse und Messen" to the end of the concluding section of the second part on "Klassische Physik und Quantenphysik". A third part of the volume, some 30 pages in length, is devoted to the subject of the extent and significance of physical knowledge.

Descriptions of physical instruments are terse, clear and confined to essentials; the mathematical arguments are of an elementary kind, involving at most one or two simple differentiations and integrations, and the balance is well kept between the different main sections of physics.

The book will provide good practice for a student anxious to obtain fluency in reading German. A. F.

2. *The cyclotron.* The cyclotron of Lawrence accelerates light nuclei to very high speeds by multiple accelerations through a small potential of 20,000 volts or so. Two *D*-shaped electrodes, fed with high-frequency alternating current, are placed in a strong magnetic field which causes the particles to curve back repeatedly through the accelerating field. In this way protons and deuterons can attain speeds corresponding to 5 million volts and more. Using ion currents less than 100 microamperes, the cyclotron has furnished the most powerful neutron beams yet obtained, with which most of the biological work to date has been carried out. Its size is remarkably small for its performance; the whole apparatus, complete with high-frequency oscillator for supplying the electrodes, can be placed in a room of modest dimensions. The power consumption is heavy, about 30 kilowatts being required for the electromagnet and 70 kilowatts for the oscillator. The magnet may weigh as much as 100 tons. The cost is high, and a skilled staff is required to run it.



THE 5 MILLION VOLT ELECTROSTATIC GENERATOR OF THE CARNEGIE INSTITUTION, WASHINGTON, D.C., IN COURSE OF CONSTRUCTION (SEPTEMBER 1937). The charging belts and ion accelerating tube will be mounted vertically inside the pear-shaped tank 55 feet high by 37½ feet in diameter, and worked under an air pressure of 50 lb./sq. in. The target and observation room are underground for protection purposes. (By kind permission of the Director.)

The cyclotron is not, of course, suitable for accelerating electrons for X-ray production. There are about 25 cyclotrons being built in the world: two of them are in England (Cambridge and Liverpool), intended primarily for physics research.

3. *Electrostatic generator.* Through the efforts of numerous workers in the United States, the old-fashioned electrostatic generator of the Holtz type has been revived and developed into a formidable high-voltage generator. A well-insulated hollow conductor is charged by swiftly moving endless belts of silk or rubber on which electric charges have been sprayed by corona discharge from a set of points kept at a potential of 10,000–20,000 volts. The voltage attainable is limited only by the breakdown of the surrounding air or by sparking along the insulators, the current being proportional to the size, number and speed of the charging belts. A large generator of this kind has been installed at the Massachusetts Institute of Technology, developing 5 million volts (one terminal 2·5 million volts positive, the other 2·5 million volts negative, to earth) and a current of 2 milliamperes.

A great advance was made by Herb, Parkinson and Kerst, of Madison University, Wisconsin, who enclosed an electrostatic generator together with an ion accelerating tube in an earthed steel tank, and worked them under an air pressure of 100 lb./sq. in. By this means, the breakdown voltage was increased to nearly four times its value at atmospheric pressure and a steady voltage was obtained of 2·1 millions to earth in a tank 20 ft. long by 6 ft. in diameter. Naturally, in this form the apparatus is independent of the humidity of the external air.

Nuclear Physics and Medicine

Modern High-Voltage Equipment in the United States and on the Continent of Europe

By L. G. Grimmett, Radium Beam Therapy Research, London*

MANY interesting developments in radiology may be expected during the next few years, as a consequence of the discovery of the neutron and of artificial radioactivity.

The neutron has peculiar and novel properties which may make it of particular value in radiation therapy. To mention only two: it is more heavily absorbed in the hydrogenous tissues of the body than in the bones, and it ionizes by means of recoil protons which give densely ionized tracks, in striking contrast to the characteristics of X- and gamma-radiation, where absorption is roughly proportional to the density of the absorbing medium, and ionization proceeds by means of thinly ionized recoil electron tracks. For these reasons alone it might be anticipated that neutrons would produce different biological effects from X-rays. Indeed, the preliminary experiments of Lawrence and his collaborators on the effects of intense neutron beams on wheat seedlings, mouse tumours and other living organisms, indicate that neutrons are more effective biologically than X-rays, and what is perhaps more significant for therapeutical purposes, that they have a greater 'selective action' than X-rays; that is to say, they inflict relatively greater damage on malignant cells than on normal ones.

Artificial radio-elements have already proved their worth as chemical and biological indicators. Elements can be 'labelled' by mixing with them a small quantity of a radioactive isotope, and their subsequent history traced through the most complicated chemical actions by means of the associated radioactivity. In this way, for example, the metabolism of calcium and phosphorus in the body of the rat have been studied.

Now that it is becoming possible to produce short-lived radioactive isotopes of the common elements in large quantities, measurable in millicuries, we may hope to extend the scope of chemotherapy by the use of radioactive organic compounds, the therapeutic action of which would depend on their radioactivity rather than on their chemical properties.

The recent advances in pure physics are thus of considerable interest to medical science, and I was glad, therefore, to have had the opportunity, through the generosity of the Prophit Trust of the Royal College of Surgeons, of visiting many institutions abroad to see what progress had been made in this kind of work. My impressions are given below; it is only possible in this short article to summarize the chief points of interest.

Production of Intense Neutron Beams and of Radio-elements

The methods commonly employed for producing intense neutron beams are the bombardment of deuterium, beryllium or lithium by swift deuterons, the probable reactions being:

$$1.\quad {}^{2}_{1}\mathrm{D} + {}^{2}_{1}\mathrm{D} \rightarrow {}^{3}_{2}\mathrm{He} + {}^{1}_{0}n$$

$$2.\quad {}^{9}_{4}\mathrm{Be} + {}^{2}_{1}\mathrm{D} \rightarrow {}^{10}_{5}\mathrm{B} + {}^{1}_{0}n$$

$$3.\quad \begin{cases} {}^{7}_{3}\mathrm{Li} + {}^{2}_{1}\mathrm{D} \rightarrow {}^{8}_{4}\mathrm{Be} + {}^{1}_{0}n \\ {}^{7}_{3}\mathrm{Li} + {}^{2}_{1}\mathrm{D} \rightarrow 2\,{}^{4}_{2}\mathrm{He} + {}^{1}_{0}n \end{cases}$$

The efficiency of the last three reactions increases rapidly with the speed of the impinging deuterons.

Neutrons are also liberated in large numbers when beryllium is bombarded with gamma rays of energy greater than 1·4 million volts.

Radio-elements can be synthesized in a great variety of ways, by bombarding elements with neutrons, protons, deuterons or helium nuclei. Here again, the neutron method apart, the efficiency of most reactions increases rapidly with the energy of the bombarding particles. It is essential, therefore, to have means of accelerating light nuclei by potentials of the order 1–5 million volts.

The chief types of apparatus for producing high-energy particles are:

1. *Cascade transformer.* This was one of the earliest types of high-voltage generators, developed by Lauritsen at Pasadena in 1928 for X-ray production at 750 kilovolts, and extended later to 1 million volts. The greatest voltage which has been reached anywhere by this method is about 2 million. The apparatus is large and costly and requires a special building to house it. Currents up to 30 milliamperes can easily be obtained, but they are alternating, which is a disadvantage for many purposes. It is doubtful whether any more cascaded transformers will be built for nuclear physics, in view of the rapid developments of alternative methods.

---

* Published by permission of the Executive Committee of the Radium Beam Therapy Research, London.

The design of this and other high-voltage machines is likely to be influenced by the discovery of the remarkable insulating properties of the gas CCl_2F_2, known commercially as a refrigerant under the name "freeon". The breakdown voltage of freeon is two to three times greater than air, and by using this gas under pressure it is possible to increase the breakdown voltage by a factor of 10.

Tuve, of the Carnegie Institution of Washington, D.C., is building a large electrostatic generator working in compressed air (see accompanying illustration). It is expected that voltages in excess of 5 millions will be obtained. The target of the ion tube is at earth potential and is underground, for protection purposes.

The electrostatic generator is relatively cheap, simple and robust. It is beginning to be adopted for hospital use; the Huntingdon Memorial Hospital, Boston, has installed one to work an X-ray tube at 1·2 million volts, 3 milliamperes.

4. *Resonance generator.* So far this ingenious apparatus, due to Sloan, has only been applied to X-ray production. Insulation difficulties are avoided by hanging a copper coil from one end in an evacuated earthed steel tank, about 4 ft. across, and making it resonate with a 100 kilowatt radio-frequency oscillator mounted above it, but not connected to it. High-frequency oscillations are induced in the coil, and an alternating potential of about 1 million volts is developed at the free end of the coil, which carries a target. The target faces a hot filament in the wall of the tank, which is biased so that electrons are accelerated only during the peak values of the alternating voltage. The apparatus is compact, but the power consumption is great (100 kilowatts). There is one of these generators in San Francisco, and another at Columbia University, New York.

5. *Cascade generators (voltage multipliers).* Greinacher, Cockcroft and Walton, and Bouwers, developed independently the cascade generator, an arrangement of condensers and rectifying valves by means of which an alternating potential of 200 kilovolts or so may be multiplied many times and rectified.

Bouwers has succeeded in getting 1·5 million volts constant potential to earth by this method at Philips' Laboratories, Eindhoven, and contemplates 2 million volts to earth in the near future.

The apparatus is on the large side and is expensive, but can be bought ready for use, and certainly has an impressive performance. It is independent of climatic conditions, has an ample reserve of power, and costs little to run.

At the moment, no ion tube is available at Eindhoven which will stand up to these voltages, but Bouwers, Heyn and Kuntke have constructed ion tubes to work at 300 and 600 kilovolts, yielding more than 1 milliampere of positive ion current, giving neutrons equivalent to 100 gm. of radium and beryllium. Even this, however, is a rather small neutron output for biological work, and some of the biological results obtained with it were criticized at the Fifth International Congress of Radiology (Chicago 1937), on these grounds.

Prof. P. Debye is installing a Siemens cascade generator in the new Kaiser Wilhelm Institute at Dahlem, for studying the materialization of gamma rays; it is in two halves, each giving 1·4 million volts to earth, with a total of 2·8 millions between the ends.

6. *Impulse generators.* Impulse generators working up to 2 million volts have been used for a long time in electrical engineering for the testing of transformers and insulators. The method consists of charging a number of condensers in parallel to 50,000 volts or so, and then discharging them in series, when a momentary voltage equal to the sum of voltages of the separate condensers is obtained. The apparatus is usually quite big and necessitates a special building, the output is under imperfect control, and is not suitable for exact physical experiments. Prof. F. Joliot, however, has turned it to good account in the manufacture of artificial radio-elements. At the Laboratoire Ampère, Paris, he has an impulse generator capable of giving 3 million volts, which is applied to an oil-immersed multi-sectioned X-ray tube of the Brasch and Lange type, about 1¼ metres long. The target of the tube is surrounded by beryllium. The heavy bursts of X-rays which occur at each impulse liberate photo-neutrons from the beryllium, which activate elements placed near by. Quantities of radio-elements approaching a millicurie have been obtained in this manner, and it is hoped to increase the yield by improving the tube design.

Incidentally, Prof. Joliot has solved the difficult problem of selecting the best apparatus for nuclear physics by installing one of each! His new Laboratory of Nuclear Physics, Paris, which is nearing completion, will have at its disposal a cyclotron, cascade generator, 2 million volt cascade transformer, 5 million volt electrostatic generator (recently a popular spectacle at the Palais de la Découverte of the Paris Exposition 1937) together with the impulse generator just mentioned. An extensive scheme of biological research is being planned in collaboration with the Radium Institute of Paris.

High-voltage X-ray equipment. X-ray apparatus for therapeutical purposes is still being developed towards higher and higher voltages, in the belief that the shorter wave-lengths are superior in their biological effects. There is a welcome tendency towards reducing the dimensions of the equipment. Bouwers described at the Congress of Radiology a million-volt installation, with sealed-off X-ray tube, measuring only 10 ft. × 8 ft. × 6 ft. high.

When the voltage has been pushed a little higher we shall be within sight of an efficient substitute for the natural gamma rays of radium (the radiation spectrum of which extends to about 2 million volts), at a price within the reach of the smaller hospitals, which cannot afford to buy large quantities of radium.

The main impression left by this tour is of the vigour with which the new physical knowledge is being followed up abroad, and applied to biology. One cannot but be struck with the absence of similar efforts in Great Britain, where, apart from a 400 kilovolt neutron generator which is being built at Mount Vernon Hospital, Middlesex, and the 1 million volt X-ray plant at St. Bartholomew's Hospital, London, no work of this kind is going on at all.

It is to be deplored that there is no institution in England where these important physico-medical problems can be attacked with the thoroughness they deserve.

Resonance and Mesomerism

By Prof. C. K. Ingold, F.R.S.

MESOMERISM is an extension of valency theory, and, like all valency theory, is founded in the quantum theory.

It may be recalled that in the quantum theory it is shown to be impossible accurately to specify the position and motion of an electron at each instant of time. What can be known about an electron, considered as a particle, is of a statistical nature, and is summarized in the behaviour of a wave. The frequency of the wave measures the energy of the electron ($E = h\nu$) and the amplitude measures the probability that the electron is in a given elementary volume (prob. = $|\psi|^2 dv$). The fundamental wave-property in the theory of the *atom* is *self-interference*—the self-interference of a confined wave; this annihilates all frequencies except those that can form standing waves, which are perpetuated and describe the quantum states. The fundamental wave-property in the theory of *valency* is *resonance*—the resonance of connected standing waves; their mutual perturbation replaces these waves by new standing waves, one of which usually corresponds to the creation or modification of some bond.

In order to appreciate the significance of resonance in the theory of valency, it is useful to recall the nature of resonance in vibrating mechanical systems. The simplest example is that of two like pendulums hung from the same stretched string. If one pendulum is given a displacement, its interaction with the string causes the vibratory motion gradually to become transferred to the second pendulum, after which it travels back to the first (Fig. 1). This motion is obviously not simple harmonic, but it can be shown to be a mixture of two simple harmonic motions. One of these occurs alone if we start the pendulums with equal amplitudes in phase; the frequency $\nu - \varepsilon$ is then a little less than the frequency ν of either uncoupled pendulum, because the two pendulums when swinging in phase deform the supporting string in mutually accommodating ways and this lowers the restoring forces. The other simple harmonic motion occurs when we start the pendulums with equal amplitudes in opposite phase; the frequency $\nu + \varepsilon$ is now a little greater than that of the uncoupled pendulums because of the opposing actions on the string. When we start the pendulums with any arbitrary amplitudes and phase difference, the two simple harmonic motions occur together, and the 'beats' arising from their differing frequencies give rise to the complicated motion described.

If ψ_1 and ψ_2 are the co-ordinates measuring the displacements of the two pendulums, then before coupling, each co-ordinate was associated with a definite frequency ν, but after coupling neither co-ordinate has any definite frequency. On the other hand, the linear combination $\psi_1 + \psi_2$ has the frequency $\nu - \varepsilon$, whilst the combination $\psi_1 - \psi_2$ has frequency $\nu + \varepsilon$. We may say that the mutual perturbation or 'resonance' has replaced the former co-ordinates of periodic motion (ψ_1 and ψ_2) by two independent linear combinations ($\psi_1 + \psi_2$ and $\psi_1 - \psi_2$), and has split the original coincident frequency (ν) into two frequencies, one greater and one less than the original.

In Fig. 1, (*A*) represents the uncoupled equivalent pendulums. Their displacement co-ordinates are ψ_1 and ψ_2, and their motion is periodic, each pendulum having the frequency ν. (*B*) and (*C*)

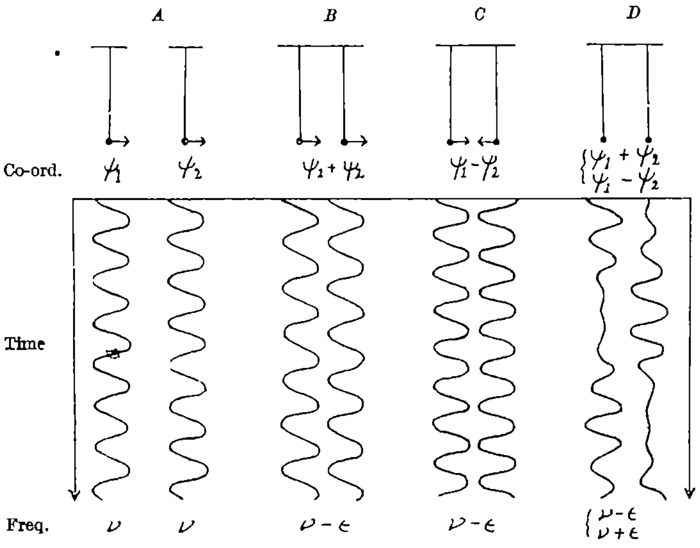


Fig. 1.

MECHANICAL RESONANCE: TIME-GRAPHS ILLUSTRATING THE BEHAVIOUR OF UNCOUPLED AND COUPLED PENDULUMS.

illustrate the only two sets of conditions in which the pendulums, when coupled, can undergo singly periodic motion. In mode (*B*) the pendulums are started with equal amplitudes in phase, and they then keep in phase; the displacement co-ordinate of the coupled system is thus $\psi_1 + \psi_2$. As the time-graph shows, the period is a little longer, and therefore the frequency, $\nu - \varepsilon$, is a little smaller, than for a single uncoupled pendulum. For mode (*C*) the pendulums must be started with equal amplitudes in opposite phase; they then remain in opposite phase, and accordingly the displacement co-ordinate is $\psi_1 - \psi_2$. As illustrated in the time-graph, the period is shorter, and the frequency, $\nu + \varepsilon$, greater, than for a single uncoupled pendulum. (*D*) represents the general result of coupling, the amplitudes and phase difference at the commencement of motion being arbitrary. Simple periodicity now disappears, but the motion can be represented as a superimposition of the periodic motions separately represented in (*B*) and (*C*). On account of the small frequency differences produced by the coupling, the superposition of these periodic motions causes the beat-like alterations of amplitude illustrated in the time-graph. Thus the general effect of the coupling is to replace two identical periodic motions by two other periodic motions, one of increased and one of decreased frequency.

If there are alternative ways in which we can supply electrons to a fixed system of atomic nuclei, and if the standing waves representing these alternatives can perturb each other, then there will be resonance. The simplest example is that of the hydrogen molecule-ion, H_2^+. There are obviously two ways of supplying an electron to a system of two hydrogen nuclei, which at first may be supposed to be fixed too far apart to admit of appreciable interaction (Fig. 2). If the electron is put near nucleus *A*, it will move in a manner represented by the standing wave ψ_A; if it is placed near nucleus *B*, it will move according to the standing wave ψ_B. The frequency of each wave corresponds to the energy of a hydrogen atom, and the form determines the probability, or charge-cloud, distribution. If now the nuclei are moved closer together so that the fringes of ψ_A and ψ_B overlap, each wave will perturb the other and neither will any longer be a standing wave of characteristic frequency. Two new standing waves will arise; one, the like-phase combination, $\psi_A + \psi_B$, which has a decreased frequency, and the other, the opposite-phase combination, $\psi_A - \psi_B$, which has an increased frequency. The former represents a system of reduced energy, a more 'stable' system, and corresponds to the formation of a bond.

Referring to Fig. 2, we have: (1) Separate ψ-waves, ψ_A and ψ_B, of identical frequency, ν, formed by supplying the electron to either of two well-separated, identical nuclei. (2) On moving the nuclei closer together the ψ-waves overlap and thus destroy each other's simple periodicity. This mutual interference, or 'coupling', gives rise to resonance, the periodic components

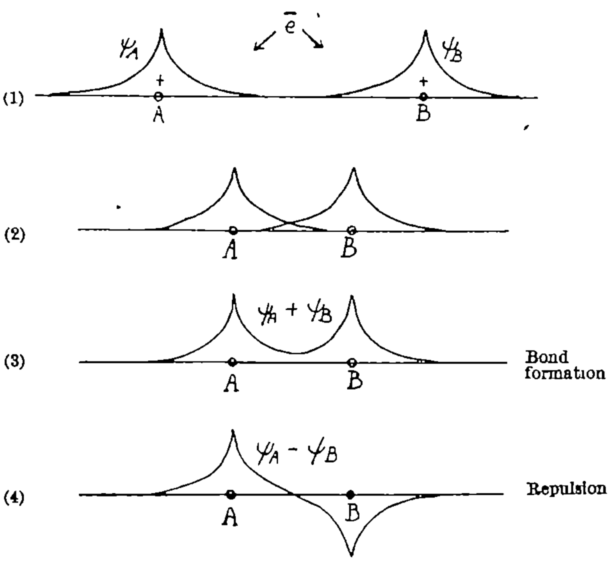

Fig. 2.

QUANTUM MECHANICAL RESONANCE: SCHEMATIC REPRESENTATION OF THE FORMATION OF A ONE-ELECTRON BOND.

of which are illustrated in (3) and (4). (3) This 'like-phase' periodic combination wave (displacement co-ordinate $\psi_A + \psi_B$) has a frequency, $\nu - \epsilon$, smaller than the frequency, ν, of the uncoupled waves ψ_A and ψ_B. The system represented thus has reduced energy: it is the molecule, which the atoms will therefore combine to form. (4) In this 'unlike-phase' combination (displacement co-ordinate $\psi_A - \psi_B$) the frequency, $\nu + \epsilon$, is greater than the frequency ν of ψ_A and ψ_B. This system has an increased energy, and represents a state from which the separated atoms will be regenerated. (In all the diagrams normalization is neglected, that is, the vertical scale is left arbitrary.)

This is the wave-picture: a particle-picture of the same phenomenon may be drawn as follows. It is a direct consequence of the uncertainty principle that all particles of which the motion is restricted have vibrational energy. The uncertainty principle may be written $\Delta q . \Delta p \approx$ Planck's constant h, where Δq represents the uncertainty in the position of the particle and Δp the uncertainty in its momentum; the momentum is, of course, closely related to the kinetic energy. A particle which is confined to a very small region of space ($\Delta q \rightarrow 0$) would vibrate with a correspondingly large energy ($\Delta p \rightarrow \infty$); and in proportion as the region is expanded the energy of the particle will be reduced. By moving nuclei A and B closer together we allowed an electron, originally imprisoned in the region of ψ_A, to escape into the region of ψ_B, and this expansion of domain, in accordance with the uncertainty principle, is accompanied by a decrease of electronic energy.

SPLITTING OF ENERGY LEVELS.

These are essentially the ideas which, variously elaborated and combined with the Pauli principle, are fundamental to all valency theory. The one-electron bond, the ordinary two-electron bond, the double bond, the triple bond, van der Waals' forces, steric repulsion—all involve resonance. It is true that wave-forms describing the statistics of poly-electronic systems are difficult to represent geometrically, but we can understand, through the analogy of the one-electron case, how resonance may lead to situations of increased stability. Leaving aside, however, all these intermediate chapters in the large subject of valency theory, we must here pass from the simple one-electron bond directly to that particular case of resonance which, on account of its special importance in organic chemistry, has received a special name, namely, mesomerism.

We can regard an ordinary structural formula as a symbol of the standing wave which has been derived by taking into account all the resonance involved in the bonds of the formula, and selecting from the final linear combinations of wave-functions that which has lowest energy. Mesomerism arises when, with nuclei in fixed positions, we can write several ordinary structural formulæ; for in this case the corresponding 'final' combination waves are not really final. They have to be linearly combined once more, with a further delocalization of the electrons, and a further gain in stability. It is essentially as a matter of convenience rather than principle that we separate this final stage of approximation to a true description from the previous stages, these being summarized in the classical structural ideas which the conception of mesomerism attempts to improve.

As an example we may consider the amidinium ion. The standing waves corresponding to the alternative formulæ are similar ; strictly expressed they are polydimensional, but are here represented (Fig. 3) schematically in one dimension. The final combination wave is a mixture of equal proportions of the two, and hence the charge-cloud distribution may be described as intermediate between those corresponding to the alternative formulæ. The identical energy levels represented by the alternative formulæ are, as usual, split into a ground level which lies lower, and an excited level which lies higher, than the original coincident levels (Fig. 4). We usually speak of the ground state as "the" mesomeric state, and the energy interval between this state and that of the structural formulæ as the energy of mesomerism.

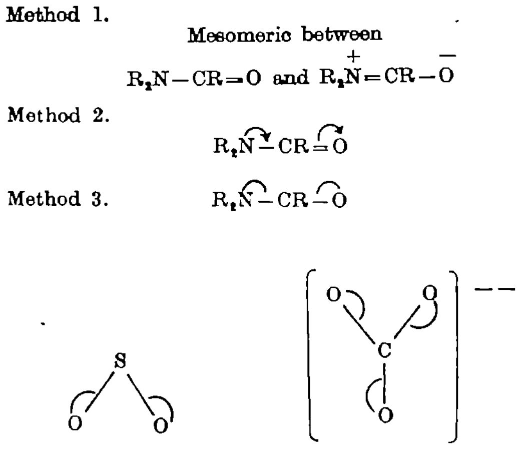

Fig. 5.
EXAMPLES OF NOTATION.

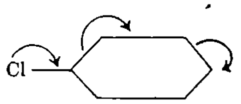
When the alternative formulæ are dissimilar, as in the amide group, there will be upper and lower initial energy levels, and the corresponding waves will not mix together in equal proportions. The combination wave of the ground state will contain an excess of the lower initial wave and that of the excited state an excess of the upper. But still the ground level will lie below the lower of the initial levels, and the charge-cloud will be intermediate between those of the initial structures.

There are several ways of expressing the intermediate character of the electron distribution in a mesomeric system. One way is to write down the various 'paper-formulæ' and to add a statement that the real formula is a mean between them (Fig. 5). A second is to write one paper-formula and attach curved arrows to it to show the direction in which it requires to be corrected. A third is to introduce a curved bond sign for each non-localized electron pair. The method chosen will depend on the example and the point which it is desired to emphasize. For example, the neatest method of expressing the trigonal symmetry of the carbonate ion is the third.

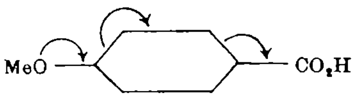
When mesomerism was first recognized (1926) as a general phenomenon in organic chemistry, it was appreciated as an electron displacement rather than as an energy disappearance : one might say that the mixing of the ψ's was perceived before the splitting of the ν's. This was because mesomerism was the electronic successor to Flurscheim's "quantitative effect", which, as he himself said, must represent a permanent redistribution of valency because it had to do with chemical equilibria, and therefore with the normal undisturbed states of molecular systems.

At that time very little was known about molecular dipole moments, but the dipole moment test for mesomeric electron displacement has since been carried out, chiefly by Sutton. He has shown that although Coulombic induction produces dipole moments in unsaturated compounds as in saturated, the former in general exhibit an extra moment, which is clearly due to mesomerism, since it always has the direction which could either have been anticipated from theory or deduced from the organic chemical observations*.

The energy disappearance characteristic of mesomerism, and its cause in electron-delocalization—the resonance of structures—was appreciated only after the fact of the polarization had been known for some years (1929). We have only to consider, however, that mesomeric polarizations, such as we can detect in chlorobenzene by dipole moments,



or in *p*-anisic acid by the acid-strengths,



in each case oppose the Coulombic induction of the substituent (Cl or MeO, both electron-attractors), in order to realize that the energy-drop which drives the polarization forward, and gives extra stability to the polarized system, must be large and independent of Coulombic energy ; therefore it must come from the only other possible source, namely, the resonance energy.

---

* More exact evaluations of the extra moment have recently been made by Sugden.

Concerning the physical evidence of the energy disappearance, it is widely known that Pauling and Sherman collected together a large body of thermochemical data which showed that the resonance energy is always negative, and may vary from quite small values up to several electron volts. The most successful attempts to calculate the energy effect of mesomerism are those of Pauling and Wheland.

Obituary Notices

Prof. G. H. F. Nuttall, F.R.S.

DR. GEORGE HENRY FALKINER NUTTALL, emeritus professor of biology in the University of Cambridge, died suddenly in London on December 16 at the age of seventy-five years.

Nuttall was born in San Francisco, where his father practised as a medical man; but later the family moved to Europe and Nuttall received his early education in England, France, Germany and Switzerland, and it was thus that he laid the foundations of his linguistic attainments. Later, Nuttall returned to the University of California, where he graduated M.D. in 1884. After a brief period at the Johns Hopkins University, he studied at Breslau and Gottingen, where he remained for four years and obtained the degree of Ph.D. At this time he became interested in botany and zoology, and these subjects led him on to the study of parasitology, to which he devoted the greater part of his life. On his return to Baltimore in 1890, he became assistant to the late Prof. Welch and later associate in hygiene at the Johns Hopkins University. In 1893 Nuttall returned to Germany and joined the Hygienic Institute of Berlin, acting as honorary assistant to Prof. Rubner. He married in 1895, Paula, daughter of Kammerherr von Oertzen-Kittendorf, Mecklenburg.

In 1899 Nuttall went to Cambridge to teach bacteriology and preventive medicine, and in the following year he was appointed University lecturer in these subjects, receiving the honorary M.A. degree. In 1906 he was appointed reader in hygiene, obtained the degree of Sc.D. and was elected a fellow of Christ's College. He held the office of reader for a few days only, being elected to the newly established Quick professorship of biology and to a professorial fellowship of Magdalene College. In 1907 the Quick Department moved into a large room on the ground floor of the east wing of the Medical School. Here in these uncomfortable quarters, which were divided up into alcoves by means of cupboards and screens, and which were known as the Quick Laboratory, Nuttall worked until 1920. In 1919, generous benefactions amounting to £30,000 from the late Mr. and Mrs. P. A. Molteno provided for the erection of the Molteno Institute for Research in Parasitology.

Nuttall received many honours; in 1904 he was elected a fellow of the Royal Society, at the same time as his friend Shipley. He also received honorary degrees from several universities. He was awarded the Belgian Order of Leopold II and the French distinction of Commandeur de la Légion d'Honneur.

Nuttall's research, incorporated in more than two hundred published papers and books, covers several branches of biology, including bacteriology, serology, hygiene, tropical medicine and parasitology. His outstanding achievement was the discovery that the blood and other body fluids possess bactericidal power, a discovery which laid the foundations of all work on serum antitoxins. In 1904 he published his classical monograph "Blood Immunity and Blood Relationship", incorporating the results of an extensive investigation of precipitin reactions carried out on some six hundred species of animal's blood. This investigation has clearly demonstrated the existence of a distinct similarity in chemical structure of the blood in animals which are related phylogenetically. It opened a new way of studying the phylogenetic relationships in the animal kingdom and provided also a new method for identification of the origin of minute traces of blood, a method which has had notable application in forensic medicine. In collaboration with Thierfelder (1895–97) he carried out the first successful experiment on life under aseptic conditions. In these investigations, guinea pigs delivered by Cæsarian section were kept alive and fed under bacteria-free conditions. These experiments solved one of the outstanding problems which preoccupied Pasteur and his pupils, and also demonstrated the origin of some organic substances in the gut and urine of animals. In collaboration with Welch (1892), he discovered and studied the first pathogenic gas-producing micro-organism causing the "gas-gangrene". This work, which came into prominence only during and after the Great War, opened a new chapter in bacteriology.

Nuttall's work on mosquitos comprises the first distribution map of *Anopheles maculipennis* in England and the discovery that this distribution coincides with the past and present distribution of malaria (ague) in England. This was followed by an important study of the biology and anatomy of *A. maculipennis*, carried out in collaboration with the late Sir Arthur Shipley. His study of canine piroplasmosis represents the first attempt of investigation in Europe of a disease imported by means of an infected vector—a tick—from South Africa. An important result of this investigation, which has great economic importance, was the discovery of the curative property of trypan blue for piroplasmosis in dogs, cattle and sheep. This study was followed by an extensive investigation of the anatomy, biology, life-history and systematics of ticks carried out in collaboration with Mr. C. Warburton, Dr. L. E. Robinson and others. Most of his time during and after the Great War was given to the study of lice (*Pediculus*), their life-history, biology and anatomy, and the problems connected with the methods of combating the spread of these parasites.

In 1901 Nuttall founded the *Journal of Hygiene* and in 1908 *Parasitology*, both of which he edited with great distinction, setting up a very high standard of publication in this field of biology. During his tenure of the Quick professorship, he raised £60,000, which was expended on building, endowment, and research, and received grants for research workers totalling nearly £12,000. On his retirement in 1932, he was presented by his colleagues and pupils with his portrait in oils painted by his friend, the late Philip de Laszló.

Nuttall had a charming manner and was a great conversationalist and excellent *raconteur*. One has a vivid recollection of him on a hot day last summer, distinguished, indefatigable and ever courteous, leading a number of French scientific investigators round the colleges and retailing in fluent French, anecdotes and stories from his apparently inexhaustible store of knowledge. He was always at ease in whatever company he found himself and had the knack of putting his companions at ease also. He was never at a loss for the right word or a courteous reply. At international gatherings he was always surrounded by numerous colleagues and was greatly helped in such company by his extensive travels and by his ability readily to speak so many languages. In spite of his multifarious activities, Nuttall found time to collect the photographs of many of the most famous parasitologists and biologists of the past, and this unique collection now adorns the walls of the corridors in the Molteno Institute. During his travels in the course of this long and active scientific career, Nuttall had exceptional opportunities of establishing contact, usually developing into friendship, with many distinguished workers of international reputation. He knew intimately several of them and had friendly scientific correspondence with others.

Nuttall's death deprives us of one of the last links with what may be described as the heroic periods in the history of bacteriology and tropical medicine. Nuttall died suddenly, as he always hoped to die, with his enthusiasm and energy little impaired and free from disabilities and sufferings often associated with old age. His wife died in 1922. He is survived by two sons and one daughter. D. K.

Capt. H. W. Seton-Karr

WE regret to record the death of Capt. H. W. Seton-Karr, archæologist, explorer and big-game hunter, who died on January 12 at the age of seventy-eight years.

Heywood Walter Seton-Karr, a member of an old Scottish family, was the son of George Berkeley Seton-Karr, resident commissioner of Baroda during the Indian Mutiny. Born in 1859, he was educated at Eton and went up to Oriel College, Oxford, afterwards entering the army. During the Egyptian campaign of the early 'eighties he served in the 92nd Regiment (afterwards the Gordon Highlanders), for which he received the medal, clasp and Khedive's star. He then travelled extensively in Egypt and Somaliland, making a large collection of palæolithic stone implements; these were among the first of extra-European origin to be recognized, and were afterwards described in the *Journal of the Anthropological Institute*. Later he made collections of similar stone implements in India. An assiduous collector, he is said to have presented collections of stone implements gathered on his travels to more than two hundred museums in various countries. In pursuit of big game he made no fewer than thirty-nine expeditions to Africa, India and Arctic Europe. He was an expert painter in water-colours and was commissioned to paint for the Imperial War Museum. His published works included "Shores and Alps of Alaska", "Ten Years' Wild Sport in Foreign Lands" and "Bear Hunting in the White Mountains".

WE regret to announce that the promising young Danish physicist Fritz Kalckar died suddenly from heart-failure a few weeks ago. Although only twenty-seven years of age, he was already one of the most brilliant collaborators of the Institute of Theoretical Physics, Copenhagen, and had written a number of interesting papers on various atomic problems. Only a few months before his death he published with Prof. Bohr, in the communications of the Copenhagen Academy, a paper on the recent development of the theory of nuclear reactions, which was intended as the first part of a series of papers on this subject.

WE regret to announce the following deaths:

Mr. H. L. Heath, formerly principal of the Mayo School of Arts and Crafts, and curator of the Lahore Museum, on February 10, aged sixty-six years.

Sir Truby King, director of child welfare, Dominion of New Zealand, 1921–27, and author of well-known standard works on the feeding and care of young children and on mothercraft, on February 9, aged seventy-nine years.

Dr. Charles Lallemand, formerly Inspecteur général des Mines, France, and president of the International Union of Geodesy and Geophysics in 1919–33, on February 1, aged eighty years.

Dr. John K. Small, director of research and curator of the New York Botanical Garden, known for his work on the flora of the United States, on January 20, aged sixty-eight years.

News and Views

Prof. Alexander McKenzie, F.R.S.

AT the end of the current session, Prof. Alexander McKenzie will retire from the chair of chemistry in University College, Dundee, which he has occupied with distinction for the past twenty-four years. After graduating in the University of St. Andrews, McKenzie began his chemical research work with Purdie at St. Andrews, and later took his degree of Ph.D. under Marckwald at Berlin. Before succeeding the late Prof. Hugh Marshall in his original university, in 1914, he held appointments as lecturer in chemistry in the University of Birmingham (1902–5) and head of the Chemistry Department at Birkbeck College, London (1905–13). In the University of St. Andrews, McKenzie has achieved a great reputation as a stimulating teacher and director of research, besides rendering valuable services over a long period as a member of Court and Senatus. McKenzie's researches in stereochemistry have earned him a well-merited international recognition as a leading authority in a branch of chemistry which has expanded so remarkably since he carried out his early researches in this field with Marckwald. He has maintained his original interest in the fundamental problems of asymmetric synthesis, and his name will always be associated with elegant work on these problems, as well as on the Walden inversion, and on the migration of organic radicals. His isolation (with Wren in 1908) of optically active benzoin may be cited as a particularly delicate stereochemical achievement, typical of his work in general. McKenzie is also known as a master in the application of the Grignard reagent and a pioneer in the vast field which was opened up by the addition of this invaluable new weapon to the armoury of organic chemistry. He will carry with him on the occasion of his retirement the cordial good wishes of his numerous circle of friends, both in Great Britain and abroad.

Sir Arthur Keith, F.R.S.

To commemorate his term of office as conservator of the Museum of the Royal College of Surgeons of England for twenty-five years, Sir Arthur Keith was presented on February 14 with a bronze bust of himself which had been made by Miss Kathleen Parbury. The bust was purchased by a large number of Sir Arthur Keith's friends and old pupils. Sir Cuthbert Wallace, in making the presentation, referred to the fundamental work of Sir Arthur Keith on the anatomy of the transmitting system of the heart and to his contributions to anthropological science during the past thirty-five years, and, in asking Sir Arthur to accept the bust, expressed the affection which all those who had subscribed, and many others, felt towards him. In his reply, Sir Arthur thanked his friends and old pupils for their generous gift, and asked the President of the College to accept the bust for safe keeping in the College Museum. After the presentation, Sir Arthur delivered a lecture on the prehistoric peoples of Palestine, the substance of which is published elsewhere in this issue.

Planning Scientific Research in Great Britain

To the January number of the *Nineteenth Century and After*, Prof. J. D. Bernal contributes an article entitled "A Policy for Scientific Research for Britain". The article is based on a memorandum on the same subject which was drawn up for the Parliamentary Science Committee by a joint committee of the British Science Guild and the Association of Scientific Workers. This memorandum was the subject of the leading article on research and finance published in NATURE of July 11, 1936. Some modifications have been made in the original memorandum, as the result of criticisms or suggestions by various individuals and scientific associations. Prof. Bernal makes an estimate of what he calls "the present budget of science in England". He arrives at a mean figure of £4,500,000, which represents only one tenth of one per cent of the national income—contrasting very unfavourably with the millions spent on advertising. In the United States the annual expenditure on scientific research is approximately £40,000,000, representing three tenths per cent of the national income or relatively three times as much as the British expenditure. Prof. Bernal puts the expenditure in the Soviet Union as only just under one per cent, and says that in Germany and in Japan it is probable that the proportional sum spent is between three and five times that of Great Britain.

IT is claimed that the present system of financing research in Great Britain does not meet the requirements of the situation and that a bolder and more comprehensive scheme is needed. The proposals of the Parliamentary Science Committee are, briefly, to form a permanent endowment fund for science, so as to ensure simultaneously: (1) adequate finance provided regularly; (2) a suitable rate of increase of income; (3) a comprehensive scheme of research covering all and not only part of the industries of the country; and (4) an organization co-ordinating the work of the different scientific departments and institutes. For these purposes, it is proposed to form a National Scientific Research Fund under the control of a Scientific Research Endowment Board, which would be an autonomous authority of the same type as the Electricity Board or the B.B.C. The Fund is to be provided jointly by the Government and industry, the Government contribution being by means of block grants from the Treasury over a number of years; and the contributions of the industrial firms might, it is suggested, take the shape of some kind of voluntary levy. One of the earliest tasks of the Board would be the planning of scientific research on a comprehensive scale. Research associations could be increased to cover all industries and might be grouped under research boards, following the example of the present Iron and Steel Research Board. In addition, it is suggested that a number of institutes for studying the fundamental aspects of applied research might be set up. It is not claimed that this proposed scheme for the endowment of science is more than a first draft, and the publication of the present proposals is intended in the first place to stimulate discussion, from which it may be hoped alternative, better balanced and more comprehensive schemes might emerge.

Drift of the Soviet Polar Station

During the last week, the drift of the Soviet Polar Station has become more rapid and on several days was as much as thirty miles. On February 11 the station was in lat. 71° 48′ N., long. 19° 52′ W., and within sight of the coast of East Greenland. *The Times* reports that the Danish authorities have sent instructions to Danes and Eskimos at the settlement at Scoresby Sound to arrange food depots along the coast in case the Russians decide that the only possible retreat is to cross the ice stream to the land. The men are now living in a snow hut, but so long as the ice stream remains compact they are in no immediate danger. Their greatest risk lies in the probability of the pack spreading and the floes being dispersed and destroyed farther south. Moreover, the southern part of East Greenland is very rugged and has no inhabitants or food depots south of Angmagsalite. If the men have to cross the ice stream to land, it is unlikely that they will be able to carry much with them. The icebreaker *Yermak* left Leningrad on February 11 and should be off the east coast about February 19. She has on board an autogyroplane, by which it is hoped a landing on a floe of restricted size will be possible. The last reports available were to the effect that the *Taimir* and the *Murman* are in constant telephonic communication with the men, but that a storm on February 14 had prevented an aerodrome being formed on the ice from which an aeroplane might start to rescue them.

Experimental Flights Across the Atlantic

The recent successful separation in the air of the seaplane *Mercury* from the flying boat *Maia* directs attention to the experimental work upon the matter of long-distance flights with commercial aircraft that is proceeding in readiness for the resumption of the Atlantic crossings during the coming summer. This combination, known as the Mayo Composite or "Pickaback" aircraft, built by Messrs. Short Bros. of Rochester, is an attempt to get a seaplane into the air with a wing loading that is prohibitively high for normal take-off, but is practicable for flight when once in the air at a safe height. The upper component is a heavily loaded seaplane that carries out the actual flight. This is carried on top of a comparatively lightly loaded flying boat capable of taking off and climbing easily and safely. When at about 5,000 feet the two separate, parting rapidly in a vertical plane, without risk of fouling or subsequent collision. Another method of attacking this problem is for the machine to start with a minimum of fuel, then sufficiently lightly loaded for safe take-off, and take on its full load of petrol from a tanker aircraft while in the air. Messrs. Imperial Airways, in co-operation with Sir Alan Cobham, have been using one of the large Empire class flying boats, the *Cambria*, for tests upon this method, with satisfactory results so far as they have gone.

A third method is to catapult the machine into the air, giving it the necessary minimum forward speed for flight by applying an impulse to it by some exterior mechanism, using hydraulic or explosive power. This, while possibly the simplest, is the least comfortable for the occupants of the aircraft. The R.A.F. have done considerable work on this, and it can be said to be successfully developed. In addition to these experiments, eight additional Empire type flying boats strengthened to carry 53,000 lb. instead of the normal 40,500 lb., have been ordered. These will have both greater fuel capacity and carry more useful load for such flights. Machines of the De Havilland "Albatross" class, a four-engined land machine specially designed for this work are also to be used.

R.A.F. High-Speed Flight

The flight by Squadron Leader J. W. Gillan, on February 10, using a Hawker "Hurricane", a R.A.F. high-speed fighter machine, directs attention to the development that has taken place, both in speeds of modern aircraft and in the methods of navigation. While this was not a properly observed speed record, in the sense that it was timed with great accuracy and afterwards reduced to a speed relative to still air, it was an ordinary flight undertaken under practical conditions upon a standard machine, and should be repeatable, under reasonable weather conditions, as circumstances demand. The flight was made in darkness, leaving Turnhouse Aerodrome, Edinburgh, at 5.5 p.m., arriving at Northolt Aerodrome, London, at 5.53 p.m. The distance was 327 miles, giving an average speed of 408·75 miles an hour, assuming the course to have been the shortest distance between the two points. This speed was helped by a high following wind of at least 50 miles an hour, although not exactly a tail wind on the line of flight. The course was flown entirely blind by the use of instruments. The "Hurricane" is fully equipped in this respect, carrying directional gyroscope, turn indicator, artificial horizon, rate of climb indicator, and a sensitive altimeter. Actually it was a real test of this method of flying, as much of the flight was made through or above cloud entirely obscuring even such landmarks as would have been visible after dark. Also the windscreen was coated with ice at certain stages of the flight, a further hindrance to vision. The machine was climbed slowly to 1 feet altitude, and maintained at that height until it was necessary to put it into a slow descent. This occurred over Bedford, one of the few towns that the pilot had been able to see through the clouds. He reported that he had been perfectly comfortable and warm, had had no occasion to use oxygen, and had no feeling of fatigue. The cockpit of this type of machine is entirely covered over with transparent cellulose material, and attention is paid to keeping the pilot warm.

Film illustrating Movement of a Fœtus

At the meeting of the Royal Society held on February 10, Sir Joseph Barcroft and D. H. Barron showed a film illustrating the development of movement in the fœtus of the sheep. The development of movement was depicted in respect of: (*a*) the types of movement which appear at different fœtal ages, and (*b*) the individuation of certain sorts of purposive movement from a general mass movement. The period of gestation is about 145 days. Up to about 35 days, the fœtus is immobile (type 1). At 35 days it commences to exhibit movements which are always 'jerky' (type 2). At 47–50 days it is almost incessant motion, which is 'sustained' (type 3). After 50 days the fœtus becomes quiescent (type 4). The following analysis may be made of these types: If the spinal cord be cut just below the brain at 60 days, without taking the fœtus out of the uterus, and the fœtus be allowed to continue growing until the cut fibres have degenerated, its body will exhibit jerky movements (type 2), whilst its head is quiescent (type 2). If the central nervous system is transected below the pons, the whole fœtus exhibits jerky movements (type 4). If the central nervous system is sectioned above the red nucleus the fœtus exhibits sustained movements (type 3). The mechanism for the integration of 'jerky' into 'sustained' movements is in the region of the red nucleus, and the mechanism for the inhibition of movement is preponderantly above that. Later parts of the film showed the development of respiratory movements (especially in relation to somatic movement), the development of progressive movement and the development of 'righting' movements.

Development of Calcutta

"The Second City of the Empire", compiled by Dr. P. C. Bagchi, has been published under the auspices of the Indian Science Congress Association as guide book and souvenir of its silver jubilee meeting recently held in Calcutta. The brochure, which is fully illustrated, gives a historical account of the rise and growth of this city and describes the development of its municipal administration, educational, industrial, public and social services. Calcutta came into existence towards the end of the seventeenth century, and largely owing to its geographical position rapidly grew into an important town. According to the 1935 census, its population now numbers more than a million. The city is mainly industrial and commercial, textiles and tea being two the chief commodities with which it is concerned. strides have been made in education during the last century, particularly since the foundation of the University in 1857. To illustrate the more modern developments on the medical side, mention may be made of the opening of the Pasteur Institute in 1924, and more recently still, the Institute of Hygiene and Public Health. The formation of the Vangiya Sahitya Parishad in 1894, for the cultivation and improvement of the Bengali language and literature, has done much to further the study of arts, while the Bose Research Institute, opened in 1917, is an example of the interest taken in pure scientific research.

The Volta Temple at Como

In *Engineering* of January 7 and 21 and February 4, Mr. F. Walker gives an account of the beautiful Volta Temple at Como, erected as a permanent memorial. The erection of the Temple was made possible by the generosity of Gr. Uff. ou Francesco Somaini, whose commission to the architect Signor Federico Frigerio placed no limits whatsoever on the class of work or expenditure involved. Standing in the public gardens near the edge of a lake in Como, the Temple is a white marble building in the Neo-Classical style, measuring approximately 25 m. in length, 20 m. in depth and 21 m. in height. The main building consists of a large circular hall surmounted by a dome, which is supported by four corner pilasters and eight marble columns. Above the capitals of the pillars is a cornice bearing in gold letters an inscription of dedication. A marble staircase leads to a mezzanuil gallery around the central rotunda, and on the parapet of the gallery are four sculptured panels illustrating incidents in Volta's life. One of these represents him demonstrating his pile to Napoleon at Paris. Though much of Volta's apparatus was destroyed in the fire at the Como Exhibition of 1899, his manuscripts and books were saved and replicas of his apparatus are shown in cases, together with many personal relics. The entire expense for the collection of apparatus has been borne by Signor Somaini, who has further endowed the Temple with a capital of 500,000 lire, the interest of which is to provide scholarships. Mr. Walker's article is accompanied with many photographs of what appears to be the most remarkable monument to any man of science.

Early Hittite Civilization in Cilicia

Results, which at first sight hold out great promise of additions to knowledge of the early stages in the extension of Hittite culture, have been obtained by the Neilson Expedition of the University of Liverpool under Prof. J. Garstang, now engaged in excavating an archæological site near Mersina on the Cilician coast of Asia Minor. A double-walled fortress has been discovered, which is thought to mark the site of a frontier post between the rival southern kingdom of Assawa and the allied State of Kizzuwadna (which seems to have included Tarsus) during the sixteenth or fifteenth century B.C., when the latter stage formed part of the realm of the Hatti, usually identified under the more familiar name of Hittites. According to a report of recent excavations (*The Times*, February 9), deep soundings on a considerable scale have disclosed no fewer than nineteen occupation-levels, belonging to a culture which, though differing, resembles that of the Hittites of the Anatolian plateau closely enough to be considered akin to it. These levels overlie a civilization which would seem to be linked culturally with predynastic Egypt and Sumer. This indicates the incoming of Hittite culture in the fourth millennium B.C., thus antedating considerably the period usually assigned to the foundation of the Hittite capital on the Anatolian plateau. Further soundings in deeper levels have disclosed an even more considerable antiquity, in which this region was evidently a centre of no little cultural activity. Although the succession of painted pottery wares and stylized patterns reflect relationship with the oldest Mesopotamian styles, there is also evidence of local development lasting over a long period. In the lowest level a rich neolithic stratum has been found, similar to that of Sakje Geuzi, in which the most characteristic features are the use of obsidian, for weapons and tools, instead of flint, and a black pottery which is thin and highly finished.

Viking Relic in the British Museum (Bloomsbury)

THE acquisition of a remarkable example of Viking art—it is, in fact, considered to be the most remarkable Viking relic now in existence outside Scandinavia—was reported at the February meeting of the Trustees of the British Museum (Bloomsbury). It is a carving in oak of the head and neck of some beaked creature which formed either the figurehead or the stern-post of a Viking ship. Its precise purpose is at present uncertain. The animal motif, usually highly conventionalized, is one of the most familiar in the decorative art of the north European peoples in the first millennium of the Christian era; but of the zoomorphs, or animal-headed figures, which are known to have adorned the Viking ships, this is believed to be the only surviving example. It is almost four feet nine inches long, and is in the form of a rounded head on a long slender neck. The head curves smoothly into a parrot-like beak, which is open and shows teeth along the edge of the mandibles. The head is well poised on the slender neck, which is covered with a deeply carved lattice pattern, presumably representing feathers or scales. The history of its rediscovery is almost as remarkable as its character. It was found some two years ago during dredging operations in the River Scheldt. Other ship's timbers were brought up at the same time, but unfortunately were not preserved. The importance of the relic was so little appreciated that it was used for some time as a garden ornament. As it is known that the Island of Walcheren at the mouth of the Scheldt was long held by Danish Vikings at the beginning of the ninth century, this zoomorph is attributed to a Danish origin.

Yorkshire 'Bygones'

A COLLECTION illustrating the past cultural history of Yorkshire in the life of both country and town has been presented to the Corporation of York and housed in the old Female Prison, which has been converted into a museum for this purpose. The donor of the collection is Dr. Kirk of Pickering. The collection includes horse brasses, horseshoes, over one hundred insurance plates, and police truncheons, some of which were used in the Chartist and Bread riots. To these have been added fireplaces of various periods, weights and measures of all kinds and periods, and a collection illustrating the history of house lighting; all these exhibits are derived from the past custom of Yorkshire. One of the most instructive is the reconstruction of a Tudor street, some one hundred feet in length, in which are doorways, mounting blocks, shops and other features collected from various parts of the county. Parts of the Female Prison, which was built at the end of the eighteenth century, have been preserved in the original state. The Museum is not yet open to the public, but a private view for subscribers was held on February 5. Among the subscribers are the Carnegie United Kingdom Trust and the Joseph Rowntree Social Trust, Ltd., from each of which the sum of £500 has been received. The historical and geographical position of York makes it a peculiarly appropriate centre for a collection of this kind. The past cultural history of a county embodies much of interest to the student of archæology and ethnology, while custom illustrating its social history survived in a primitive form down to quite recent times, of which it is still possible to find traces in the remoter districts. In these matters, it is true, Yorkshire does not stand quite alone; and although the scheme for a national folk-museum for England seems for the time being to make little progress, it is none the less gratifying to note that local collections are being made before the material has entirely disappeared, as has been shown by recent correspondence in *The Times*.

Hooke's Experiments on Combustion

IN the issue of *Ambix* of December 1937, Dr. D. J. Lysaght publishes an interesting account of Robert Hooke's theory of combustion, which he outlined in "Micrographia" (1665) and amplified in his "Lampas" (1677) and "Cutlerian Lectures" (1679). Hooke's failure to impress his views upon the members of the Royal Society is attributed to his lowly social position, the simplicity of his conceptions, and the innate conservatism of the seventeenth-century mind. Hooke wrote only a scanty account of the experiments upon which he based his ideas, and Dr. Lysaght has done a useful service to historical chemistry by giving a critical discussion of these experiments, as transcribed in Birch's "History of the Royal Society" (1756–57) from the Royal Society's "Journal Book" (1661–87). Hooke's "many luciferous experiments" sufficed to demonstrate all the important facts bearing upon the problem of combustion. "The consumption of a selected portion of the air, the necessity for a continuous supply of this fluid, the formation of heat and light by the 'composition', the existence of solids with the essential constituent of the air 'fixed' in them and available for combustion, and the increase of weight on calcination must be admitted to be almost all the evidence required for the modern theory. These phenomena were linked up with those relating to respiration. The one fact that was not understood seems to be the part played by the air in calcination . . . and this deficiency prevented the complete synthesis that appears to have been so near at hand." Dr. Lysaght concludes that Hooke's work had the effect of postponing for a considerable time the adoption of the phlogiston theory of combustion.

Unemployment in Colorado

A SURVEY of the Colorado labour market and its "relation to unemployment compensation", by E. R. Livernash of the Massachusetts Institute of Technology, has been issued in the University of Colorado Studies (24, Nos. 3 and 4; 1937). The survey was undertaken in the summer of 1936, and indicates that outside the provisions of the Act there are 45,000 agricultural labourers unemployed and 21,000 domestic servants, as well as a considerable number of those working in trading establishments employing less than eight persons. Unemployment of long duration is regarded as inadequately compensated, this type of unemployment being particularly heavy in the steel, coal and constructional industries and in declining industries such as the southern coal field. The problem of exhausted-benefit unemployment may be of major importance. The recurrent drain of seasonal unemployment, however, may be unwise, as annual earnings are often adjusted on a competitive basis. Much cyclical unemployment appears as seasonal employment, and this may mean a considerable volume of ineligible unemployment in a bad depression. The difficulty seems to be that in future depressions unemployed individuals most in need of relief will find themselves in the exhausted-benefit and ineligible classes. The law may be putting a premium on short-time recurrent unemployment. Mr. E. R. Livernash suggests that experience under the Act, enabling us to classify types of unemployment, may ultimately permit compensation being related more upon the incidence of unemployment, both in occurrence and duration.

A Nature Reserve of Fossil Plants

PROF. G. R. WIELAND made an eloquent plea (*Science*, March 19, 1937), that will be endorsed by the botanists of all countries, for the creation of a national monument on the Black Hills, U.S.A., in which specimens of the remarkable cycadeoid fossils will be exposed *in situ* for study among their natural surroundings. The magnificent photographs of these specimens previously published by Prof. Wieland are evidence how effective such a display would be. His present arguments, indicating the striking parallelisms between these plants and the types discovered in the Carpathians and the Isle of Wight and Isle of Portland and elsewhere, and directing attention to their increased significance in view of the wide vistas on floral morphology in the Gymnosperms opened by the discovery of the marvellous petrified Araucarian forest of the Cerro Cuadrado in central Patagonia, reinforce very powerfully the case for expenditure of time and money in achieving an appropriate display of these unique fossils. The locality is described as very accessible; the horizon is perfectly defined and the quarrying necessary not extensive. It is very much to be hoped that Prof. Wieland's object will be attained and the United States thus obtain a national monument that would be quite unique in its character and clear evidence that that great nation appreciates the value of some of its most remarkable scientific possessions.

London Teachers' Association

AT its annual conference held on February 12, the London Teachers' Association was addressed by its new president, Mr. S. Vanderhook, of Holden Street School, Battersea, on "Current Issues in Education" including, as "the most vital", reduction in the size of classes. The L.C.C. programme for 1938–41 contemplates a reduction of classes in junior schools to 42 and in infants' schools to 44, the standard for senior schools remaining at 40. As it is now twenty-five years since the L.C.C. initiated a scheme for reducing the size of infants' classes to 48 and senior classes to 40 Mr. Vanderhook may well call the new scheme a "small" step forward. A large part of the address has reference to the measures which are to come into operation next year for raising the permissible school-leaving age to 15. The Board of Education's Circular 1457 on this subject is discussed on the lines of the National Union of Teachers' memo. of December 1937. Mr. Vanderhook would, himself, use a short way in dealing with applications for exemption from further school attendance in order to accept "beneficial employment". He would reject them all; for he holds that there is no employment which is beneficial for young persons of fourteen years of age.

Destruction of Sea-Birds by Oil

A LIVELY and informative discussion regarding the destruction of sea-birds by oil waste took place at University College, London, in May last, under the auspices of the University of London Animal Welfare Society, and the report of the meeting has just been published (ULAWS Monographs and Reports, No. 2*a*). Prof. N. K. Adam opened the discussion. A summary of Prof. Adam's special report has already appeared in NATURE of July 17, 1937, p. 100. Many representatives of oil and shipping interests and naturalists took part in the subsequent discussion, the general tenor of which indicated that, in spite of legislation and a 50-mile limit for the discharge of oil, the amount of destruction was still very great, Prof. Adam putting the estimated death-roll of sea-birds at from 10,000 to 200,000 a year. Only international action is likely to be effective in bringing this destruction to an end, and since the maritime nations are almost entirely opposed to the compulsory fitting of oil separators to vessels, efforts are being made to prohibit the discharge of waste oil in certain areas where the effect is likely to be greatest. Mr. Sanford D. Cole described the Wheeler system by which the cleaning out of oil tanks, double bottoms and bilges is carried out mechanically and much more efficiently than by hand, and suggested that the installation at various ports of separator barges fitted with this American contrivance might go far to diminish the evil of oil pollution.

Sea Shells from Victoria

THE Field Naturalists' Club of Victoria is designing a series of handbooks to foster interest in the State's fauna and flora. The second of the series is by C. J. Gabriel, honorary conchologist, National Museum, Melbourne; it is entitled "Victorian Sea Shells, a Handbook for Collectors and Students", and has been published by the Field Naturalists' Club of Victoria (price 1*s.* 6*d.*). It is well illustrated by Joyce K. Allan, assistant conchologist, Australian Museum, Sydney, with a coloured and several uncoloured plates. Descriptions are given of most of the common sea shells around the coast of Victoria. From a collector's point of view, this little work is extremely useful and will help many to name their specimens. It does not, however, attempt to teach anything about the animals themselves beyond their various habitats. A popular name is given to each shell, in most cases a translation of the specific name. Thus we have the "impoverished Nassarius" and the "sordid sand snail", but there is the banded periwinkle, also known as the "Austral wink", and the black nerite, also known as the "crow". There are a dictionary of terms and diagrams showing the different parts of the shell.

World Congress of Faiths

THE World Congress of Faiths, of which Sir Francis Younghusband is chairman, is arranging a week-end Congress to be held at Cambridge on June 24–28, with residence for men at St. John's College and for women at Newnham College. The subject for deliberation will be "The Renaissance of Religion". Distinguished speakers, representing religions, philosophy and science, will deliver addresses to be followed by discussion. The object for which the World Congress of Faiths is organized is to promote a spirit of fellowship among mankind through religion. The Congress seeks to awaken and develop a world-loyalty, whilst allowing full play for the diversity of men, nations and faiths. Further particulars may be obtained from the secretary, World Congress of Faiths, 36 Victoria Street, London, S.W.1.

Announcements

THE Most Reverend Cardinal Arthur Hinsley, Archbishop of Westminster; Prof. J. Chadwick, professor of physics in the University of Liverpool; and Sir Richard Livingstone, president of Corpus Christi College, Oxford, since 1933 and Vice-Chancellor of the Queen's University, Belfast, in 1924–1933, have been elected members of the Athenæum under the provisions of the rule of the club which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for their public services.

H.M. THE KING has approved the award of the Royal gold medal of the Royal Institute of British Architects to Mr. Ivar Tengbom (Sweden), hon. corresponding member, in recognition of the merit of his work as an architect. The medal will be presented to Mr. Tengbom at a general meeting of the Institute on April 4.

THE following officers of the Royal Astronomical Society were elected at the anniversary meeting of the Society on February 11: *President*, Dr. H. Spencer Jones, Astronomer Royal; *Vice-Presidents*, Prof. S. Chapman, Prof. H. Dingle, Sir Frank Dyson and Prof. F. J. M. Stratton; *Treasurer*, Mr. J. H. Reynolds; *Secretaries*, Prof. W. M. H. Greaves, Prof. H. H. Plaskett; *Foreign Secretary*, Sir Arthur Eddington.

IN connexion with the movement for the preservation of the fauna and flora of the Empire, attention has been directed to the imperfection of our knowledge of the fauna and flora of Fiji and the Western Pacific High Commission Territories. These Governments have recently expressed the hope that the subject will attract more attention in future. Adequately qualified naturalists desirous of devoting a few months to such studies in these territories under favourable conditions should consult the Under Secretary of State, Colonial Office, Downing Street, S.W.1.

PROF. GÜNTHER ENDERLEIN, the well-known Berlin entomologist and bacteriologist, has recently retired on reaching the age limit.

PROF. HANS BURGER, director of the psychiatric and neurological clinic at the University of Jena, has been nominated a member of the Kaiser Leopold Caroline German Academy of Natural Science in Halle.

THE Gillson scholarship in pathology has been awarded by the Society of Apothecaries of London to Dr. R. H. S. Thompson of the Rockefeller Institute.

THE following appointments and promotions have recently been made in the Colonial Service: Agricultural officers—G. D. Badger, Uganda; T. W. Brown, Malaya; F. E. J. Buller, Nigeria; P. V. Ormiston, Malaya; W. N. Scott, Malaya; A. K. Briant (agricultural superintendent, St. Vincent), Zanzibar; R. P. Davidson (agricultural officer, Uganda), Malaya; H. P. Smart (agricultural officer, British Honduras), senior agricultural officer, Tanganyika. Other appointments—P. Coryndon, inspector of produce, Nigeria; F. E. Harnett, sleeping sickness control officer, Nigeria; J. R. O. Humphries, inspector of plants and produce, Gold Coast; D. W. Le Mare, assistant to the director of fisheries, Str Settlements.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 334.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Nuclear Photo-effects

THE beautiful experiments of Bothe and Gentner[1] on the ejection of neutrons from heavier nuclei by means of γ-rays with energy of about 17 M.v. resulting from impact of protons on lithium, have revealed a remarkable selectivity of these nuclear photo-effects. Thus a few elements, apparently irregularly distributed, were found to possess cross-sections for such effects of the order 10^{-26} cm.^{2}, while for the large majority of the elements investigated no measurable effects could so far be detected. At first sight this selectivity might, as pointed out from various sides, seem difficult to reconcile with the views on the mechanism of nuclear reactions to which one has been led through the study of the effects initiated by neutron impacts[2]. In fact, the distribution of the energy levels of the compound nucleus formed in such collisions must for all heavier elements be expected to be practically continuous for excitation energies above 10 M.v., while the nuclear photo-effects obviously demand a special sensitivity for much higher excitations confined within well-separated energy regions.

This apparent contradiction disappears, however, if we realize that the level distribution of the compound nuclei, which form the intermediate stage in nuclear transformations initiated by collisions, represents the ensemble of stationary states corresponding to the more or less coupled modes of vibration of the nucleus, while the response to the photo-effects is primarily conditioned by certain special vibratory motions with singular radiation properties. Thus, in nuclear transformations initiated by high-frequency radiation, we have not to do with a simple competition of the disintegration and radiation probabilities of a well-defined intermediate state, but rather with the balance between the radiative processes and the effect of the coupling of the corresponding specific vibrations of the nucleus and the other possible modes of nuclear vibrations. This coupling will tend to the rapid extinguishment of any special features of the initial type of excitation and to its replacement by a more stable state of the excited nucleus, where the energy is distributed among all modes of vibration in a way analogous to the heat motions of a solid body at low temperature. As soon as such a state of nuclear excitation is established, the course of the photo-effect is practically determined. In fact, the radiative properties of the nucleus in this state will resemble that of a black body with a temperature of a few million volts, and the probability that the whole energy is emitted in a single radiation quantum of 17 M.v. will accordingly be negligibly small. Moreover, for the high excitations concerned, the total probability of the radiative processes of the nucleus will be very much smaller than the probability of its tegration, which increases exponentially with the ture like in a usual evaporation process.

This argument implies that the cross-section for nuclear photo-effects in the energy region concerned will be given by a formula of the type well known from the theory of optical selective absorption:

$$\sigma = \frac{\lambda^2}{4\pi} \sum_i \frac{\Gamma_R \Gamma_C}{(\nu - \nu_i)^2 + \frac{1}{4}(\Gamma_R + \Gamma_C)^2}$$

where λ and ν are the wave-length and frequency of the γ-rays respectively, and ν_i one of the sequence of such frequencies corresponding to maximum resonance. Further, Γ_R and Γ_C are the probabilities in unit time, respectively, for the re-emission of a quantum $h\nu$ from the initial special state of excitation of the nucleus and for the conversion of this transitory state to the ordinary state of nuclear excitation with the same energy. This latter process will be seen to correspond closely to the effect of collisions in diminishing the resonance in absorption of light in gases at high pressures.

Present experimental evidence does not directly disclose for any given element the variation of the cross-section of the selective photo-effect with the frequency of the γ-rays. Still, from the way in which this cross-section varies among the elements for rays with $h\nu = 17$ M.v., it would appear that the distance between the resonance maxima in this energy region is probably some million volts and that the breadth of each of these maxima is roughly comparable with the variation of $h\nu$ in the incident γ-rays due to natural width of the line and the Doppler effect in the proton-lithium collision which amounts to about 50,000 volts. If, further, the largest cross-sections observed are assumed to correspond to maximum resonance, we get from the above formula values for Γ_R and Γ_C of the order of magnitude 10^{15} sec.$^{-1}$ and 10^{19} sec.$^{-1}$ respectively. Both these values appear quite reasonable. In fact, on account of the high frequency of the γ-rays concerned, we should expect Γ_R to be several times as large as the probability of emission of ordinary γ-rays in nuclear transmutations, estimated from neutron captures to be about 10^{14} sec.$^{-1}$. Further, the value for Γ_C is much smaller than the frequency 10^{21} sec.$^{-1}$ of the initiating γ-rays, while it is much larger than the probability of disintegration of the excited nucleus, estimated by the evaporation analogy to be of the order 10^{16} sec.$^{-1}$ for energies of about 17 M.v.

The proportion between the duration of the initial transitory state and the whole lifetime of the excited nucleus, which for 17 M.v. is thus probably of the order 10^{-3}, should for lower energies be still smaller, since the coupling between the different modes of vibration will presumably decrease much more slowly than the probability of neutron escape. At the same time the ratio between the chances of re-emission of a quantum $h\nu$ from the initial state of excitation and from the more stable state of the excited nucleus will rapidly decrease. Still this ratio, which for 17 M.v. is extremely large, will scarcely approach unity before we have come well within the energy region of discrete nuclear levels. Even in the upper part of this region, we must therefore be prepared to find a selectivity of the nuclear photo-effect similar to that found in the continuous energy region, but in experiments with sufficient monochromatic γ-rays each resonance maximum will here resolve itself into a fine band of sharp absorption lines corresponding to the separate levels. With the vanishing predominance of the initial state of excitation with regard to the radiation processes, this kind of selectivity, however, will soon disappear and be replaced by a line absorption spectrum of the usual type, which of course will be accompanied by a nuclear photo-effect only so long as $h\nu$ is large enough to cause a disintegration of the nucleus.

In the discussion of these problems, of which a more detailed account will be given in a forthcoming paper in the communications of the Copenhagen Academy of Sciences, I am indebted to my collaborators of the Institute of Theoretical Physics for valuable help, especially to Mr. Fritz Kalckar, whose sudden death a few weeks ago means a most regrettable loss to us all*.

Relativity and Quantum Theory

IT is well known that the transformation theory of quantum mechanics corresponds to the property of the classical equations of motion of being invariant with respect to contact transformations. These are simultaneous transformations of co-ordinates x^k (including time) and momenta p_k (including energy), such that the difference of $p_k dx^k$ in the old and in the new variables is a total differential. The point transformations in the x-space are only a special case; but there exists another case of the same simplicity which can be described as a point transformation in the p-space.

General relativity, on the other hand, is concerned only with point transformations in the x-space; it can easily be seen that the transformation of the p_k induced by the contact condition mentioned above is exactly equivalent to the tensor calculus of relativity. It has struck me that the point transformations in the p-space might be considered in the same way. Thus one is led to a kind of inverted relativity formalism in the p-space in which everywhere space-time and momentum-energy are interchanged. The principle laws of quantum mechanics, such as the commutation laws, the relations of indeterminacy, etc., are symmetrical in x^k and p_k.

These facts suggest very strongly the formulation of a 'principle of reciprocity', according to which each general law in the x-space has an 'inverse image' in the p-space, in the first instance the laws of relativity. The foundation of this idea is too involved to be explained here; it is developed in a paper which has been submitted to the Royal Society. I wish only to press the point that this theory attempts to explain the ultimate particles on relativity considerations without connecting them with the whole universe (x-space)—an idea[1] which seems to me unacceptable for reasons of physical common-sense.

I shall now indicate some simple consequences and numerical results. The principle of reciprocity leads to the introduction of a metric tensor γ_{kl} in the p-space, the coefficients of which are not given numbers but functions in this space which satisfy differential equations in exact analogy to Einstein's gravitational equations for the g_{kl}. The most general form of these contains a 'cosmological term' due to which the x-world is closed and has a finite radius a. The corresponding property of the p-space is this: an energetically closed system corresponds to a closed momentum space, with a radius b, which represents the maximum momentum possible. There are several attempts in the literature[2] to introduce such a maximum momentum, with the purpose of eliminating the disturbing 'infinities' in quantum mechanics; but they had to be rejected since they contradicted relativity. This difficulty is avoided with help of the new principle.

Between the g_{kl} (multiplied by a proper constant A) and the γ_{kl} (divided by A) there will be a relation which is the quantum equivalent of contact transformation, of the form

$$Ag(x) = h^{-3/2} \iiint \frac{1}{A}\gamma(p)\sqrt{-|\gamma|}\, dp_x dp_y dp_z,$$

where $|\gamma|$ is the determinant of the γ_{kl}. In order that g_{kl} and γ_{kl} be dimensionless numbers, one has

$$A^2 = (b/\sqrt{h})^3.$$

The chief consequence of the closed p-space is a change of the expression for the number of quantum cells of a given phase element. This new formula has a great number of applications. The following quantities which are infinite in the accepted theories become finite: The number n of quantum states of radiation in the x-volume V, the zero energy ε of the radiation in V, the self-energy $e^2/r_0 = mc^2$ of the electron; taking the empirical values for c, e, m, one has numerically

$$n = n_0 V, \qquad \varepsilon = \varepsilon_0 n = \varepsilon_0 n_0 V,$$
$$n_0 = 2{\cdot}90 \times 10^{37} \text{ cm.}^{-3}, \qquad \varepsilon_0 = 59{\cdot}7 \text{ M.e.v.}$$

Between the natural units of length and momentum, r_0 and b, and the quantum constants h and A (defined above), there are the symmetrical relations

$$h = (\pi r_0)b, \quad A^{4/3} = \frac{b}{\pi r_0} = 0{\cdot}0085 \text{ gm./sec.}$$

Coulomb's law is modified by a factor $\int_0^{2r/r_0} J_0(x)dx$, where $J_0(x)$ is the Bessel function. This implies a change of Rutherford's law of scattering, to which is added a factor

$$\left(1 - \frac{E}{E_0}\sin^2\theta/2\right)^{-1}.$$

where E is the energy of the incident particle, and E_0 a constant energy which equals 19·200 M.e.v. for the proton-electron collision; for the proton-proton collision where the formula has to be modified (exchange effect) the characteristic energy is 10·4 M.e.v. in good agreement with experimental results[3].

There are further deviations from Planck's and Stephan-Boltzmann's laws; the latter resembles for high temperatures the formula for the heat content of a crystal, with the characteristic temperature

$$\Theta_0 = 1{\cdot}63 \times 10^{12} \text{ degree.}$$

These deviations are connected with the fact that the pressure of radiation is not equal to $\frac{1}{3}$ of the energy density; Maxwell's equations do not hold in these domains.

The laws of the kinetic theory of gases undergo also an alteration, which for a gas of molecular weight μ begins at a characteristic temperature

$$\Theta = \frac{137}{1845}\,\frac{\Theta_0}{\mu} = \frac{1{\cdot}21 \times 10^{11}}{\mu} \text{ degree.}$$

The equation of state is unchanged, but the specific heat goes to zero for $T \rightarrow \infty$.

The application of the new principle to the structure of nuclei leads to interesting results. A nucleus of mass number A is considered as the densest packing of A particles of mass number 1 (protons, neutrons). Then the radius R of the nucleus is connected with the electronic radius r_0 by

$$R = r_0\sqrt[3]{\tfrac{3}{8}A} = 2{\cdot}02 \times 10^{-13}\sqrt[3]{A} \text{ cm.,}$$

in excellent agreement with Bethe's[4] estimate $(2{\cdot}05 \times 10^{-13})$. The mean kinetic energy $\bar{\varepsilon}$ per nuclear particle (proton or neutron) and the maximum energy ε_0 are given by

$$\varepsilon_0 = \tfrac{5}{3}\,\bar{\varepsilon} = 10{\cdot}4 \text{ M.e.v.}$$

The application of the Fermi distribution law together with Bethe's empirical value for the radius leads to $\varepsilon_2 = 10$ M.e.v.

These confirmations show that we have to do with more than a mere formalism. Though we are at present far from having a consistent theory, the new principle provides an attractive programme of investigation.

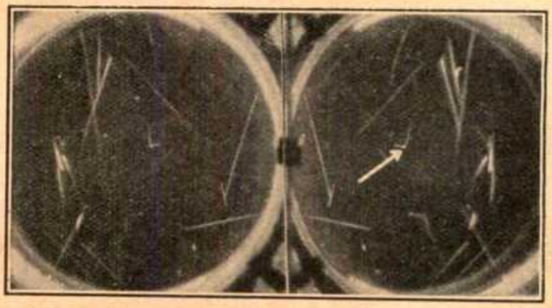
Wilson Chamber Photograph of the Neutro-Electric Effect

AMONG the possible interpretations of the neutro-electric effect, recently discovered by Kikuchi, Aoki and Husimi[1], the disintegration of the neutron into an electron and a proton must be discarded, since Gilbert, Smith and Fremlin[2] could find no corresponding track in the Wilson chamber. (Their estimation that about thirty proton-electron pairs should appear per expansion is no doubt too large; but our present result is also in contradiction to the view of disintegration.) The most reasonable explanation would be to assume the expulsion of the orbital electron or the electron in a negative state due to some still unknown interaction between the electron and heavy particles. In this process, as the neutron loses its energy, the atom with which collision has occurred should gain the corresponding momentum. Therefore, the electron track starting in the Wilson chamber should always be accompanied by a track of a heavy particle.

We searched for such kind of tracks in a Wilson chamber placed near the D–D neutron source filled with methane mixed with alcohol vapour. According to our previous result, the cross-section of the proton for the process is $0{\cdot}6 \times 10^{-26}$ cm.^{2}. Assuming the cross-section for the elastic scattering to be $2{\cdot}0 \times 10^{-24}$ cm.^{2}, 1 in 300 recoil proton tracks should appear in pair with an electron track. From the atomic concentration of the carbon atoms in the chamber and the known cross-section, the ratio of the number of carbon-electron pairs to that of single proton tracks in the same photographs should be about 1 in 200.



WILSON CHAMBER PHOTOGRAPH OF THE NEUTRO-ELECTRIC EFFECT. THE NEUTRON TRAVELS UPWARDS.

We examined about 900 pairs of photographs and obtained 3,060 proton tracks starting from the illuminated portion of the chamber. Of these, six appeared with the electron track. The accompanying illustration shows one of the photographs obtained. The number of the tracks which should be attributed to the carbon-electron pair was 12. These figures are in good agreement with our expectation. For various reasons it is impossible to consider that all the pairs we have observed are due to accidental coincidence of two independent tracks.

There now seems to be no doubt about the reality of the new effect. Its importance in connexion with the theory of the elementary particles can scarcely be over-estimated.

A Non-radiating Motion of a Spinning Electron

MATHISSON[1] recently deduced the equations of motion of a spinning electron from the General Theory of Relativity. According to those equations such a particle, when free, instead of following a geodesic, performs some sort of screw motion around it. In the special case when the 'gravitational background' is the space time of the Special Theory of Relativity and the velocity is small compared to the velocity of light, this movement consists of a uniform translation in any direction and a uniform circular motion in a plane perpendicular to the angular momentum $\mathbf{J}$ of the particle, the frequency ν being proportional to $\mathbf{J}$. The radius remains indeterminate. Assuming $\mathbf{J} = h/4\pi$ we get $\nu = 2m_0c^2/h$.

If this particle had the mass m_0 and the charge $-e$ of an electron, the radiation damping of its circular motion would be so great as to stop it almost immediately. Mathisson's attempts to establish a connexion between the Theory of Relativity and quantum mechanics would then obviously encounter unsurmountable difficulties. In the course of a private discussion, Dr. Mathisson expressed, therefore, the view that not only the mass, charge and spin of the particle but also its magnetic moment should be taken into account. It is to be expected, then, that the electronic constants might be chosen in such a way that a free electron would not emit any radiation when moving in the above-mentioned manner. Mathisson is now completing his theory on these lines.

It is possible to show in a very simple 'classical' way that in some particular cases the superimposed action of a magnetic dipole can annihilate the radiation of an electric charge in motion. It is well known that when a magnetic dipole with a moment **q** moves with a velocity **v**, an electric moment

$$\mathbf{p} = \frac{1}{c}\left[\mathbf{vq}\right] \qquad (1)$$

appears. Suppose such a magnetic dipole carrying also an electric charge $-e$ moves uniformly around a circular orbit of radius r, the frequency being ν and the dipole axis remaining perpendicular to the plane of the circle, the electric moment (1) will then be directed along the radius vector of the particle. If we put

$$p = er \qquad (2)$$

and assume that the sense of motion is such as to produce a magnetic moment opposite to **q**, the action of the resulting electric moment will be equivalent, at sufficiently distant points, to that of a charge $-e$ in the centre of the circle and a charge $+e$ on the particle. The moving electron charge will be compensated and there will remain only a charge $-e$ at rest in the centre of the circle. At distances large enough there will remain thus only an electrostatic field and the radiation will disappear. Putting $\mathbf{q} = \frac{h}{4\pi}\frac{e}{m_0 c}$ and $\mathbf{v} = 2\pi\nu r$, we get from (1) and (2)

$$\nu = 2m_0c^2/h.$$

Curiously enough, this is also the frequency of Schrödinger's *Zitterbewegung* for a Dirac electron in slow motion.

The above considerations seem to me suggestive, though—or rather because—they are based on such crude 'classical' notions.

Coupling between the Orbital and the Spin Angular Momenta of Paramagnetic Ions from Magnetic Measurements

IN a salt of the iron group, though the spin angular momentum of the paramagnetic ion is not directly affected by the crystalline electric fields acting on the ion, yet indirectly it is, owing to its coupling with the orbital angular momentum of the ion, which is easily affected by these fields. The magnetic anisotropy of the crystal, and the deviations of the temperature dependence of its principal susceptibilities from the Curie law, are the results of such an indirect influence of the crystal fields on the spin angular momentum exerted through the spin-orbit coupling[1], and should be the greater the stronger the coupling. Conversely, from the observed anisotropy or the deviations from the Curie law, it should be possible to calculate the strength of the spin-orbit coupling in the ion.

Such a calculation is simple for a nickel salt, and the necessary theoretical expressions have been worked out by Penney and Schlapp[2]. The magnetic anisotropy $\Delta\chi$ for any given plane in the crystal, that is, the difference between the maximum and the minimum susceptibilities in the plane, per gram molecule, is given by the relation

$$\Delta\chi = \frac{8N\beta^2}{3kT}\left(8\lambda - \frac{2\lambda^2}{kT} - 3kT\right) . \Delta\alpha,$$

where λ is the constant of spin-orbit coupling, β is the Bohr magneton, and N, k and T have their usual significance. The factor $\Delta\alpha$ depends on the crystal fields acting on the Ni^{++} ions, and on the orientation of the selected plane in the crystal. Because of the small coefficient of thermal expansion of the crystal, $\Delta\alpha$ will be almost independent of temperature. From measurements on $\Delta\chi$ at two different temperatures it should therefore be possible to eliminate $\Delta\alpha$ and determine λ.

Using the method described by us in some recent papers[3], we have measured the magnetic anisotropies of the tetragonal crystals $NiSO_4.6H_2O$ and $NiSeO_4.6H_2O$, at the temperature of liquid oxygen and at room temperature. For both the crystals the anisotropy at $-183°$ C. is found to be about $4{\cdot}8_0$ times that at 23° C. From this ratio we obtain for the constant of spin-orbit coupling in Ni^{++} the value $\lambda = -331$ cm.$^{-1}$, which agrees well with the value -335 cm.$^{-1}$ obtained from spectroscopic data[4].

Diffraction Gratings ruled in Metallic Films

PROF. R. W. WOOD, of Johns Hopkins University, has recently reported[1] on the successful preparation of diffraction gratings by ruling on 'aluminized' surfaces, and predicts a bright future for this type of dispersive instrument. One of the most interesting aspects of this technique, however, is not included in his letter. Inasmuch as I participated in the conception and development of the general method of preparing and ruling evaporated films at Cornell University early in 1934, which method Prof. Wood was induced to adopt about a year later, I feel that I am in a position to offer some comments of interest.

Diffraction gratings are not ruled upon 'aluminized' mirrors but rather upon mirrors the surfaces of which are coated with a discrete film of aluminium deposited over a film of chromium. It was found in the early attempts to rule gratings in evaporated films of pure aluminium that the aluminium film was stripped in patches from the glass by the diamond point, while films of pure chromium were so hard that a diamond loaded heavily enough to rule the chromium also disfigured the surface of the glass underneath. Hence it was rightly concluded that a double film might serve, since the diamond could be caused to rule through the soft aluminium without being loaded heavily enough to affect the under-coating of chromium. At the same time the aluminium-chromium bond would not be disturbed, for the tenacity of an aluminium film for one of chromium is far greater than that of an aluminium film for glass. It is of interest to note here that this search for a proper film for ruling diffraction gratings has led to the development of a type of film, called 'chroluminum', now extensively used for coating large astronomical mirrors.

The double film has ideal properties for the ruling of diffraction gratings in that the glass surface is not touched by the diamond point, and in that the depth of the rulings can be controlled accurately by controlling the thickness of the aluminium film. The first property allows the same figured and polished mirror blank to be used over again in case the first ruling is a failure, since the chroluminum surface can be removed easily from the glass and a new one deposited for another try at ruling. The second property allows rulings of any desired depth to be obtained with comparative ease, and thus allows most of the light of the reflected spectra to be concentrated in a desired colour of a desired order. The thickness of the aluminium film through which the diamond point is to rule is computed in advance, and is controlled during the process of deposition of the aluminium. The thickness of the underlying chromium film is of little importance, and is usually made slightly less than that necessary to give opacity.

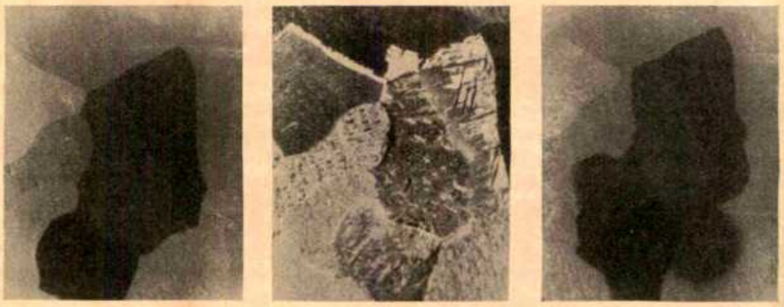
Electron-Optical Observation of the Transition of α- into β-Zirconium

THE investigation of the transformation process of the hexagonal α- into the cubic β-modification of zirconium by means of X-rays[1] led to the conclusion that this process is brought about by a homogeneous transformation (shearing combined with dilation) of coherent lattice regions parallel to definite crystallographic planes and directions, the 'shearing motion' being opposed in successive α → β and β → α transitions, the whole process thus resembling closely the way martensite needles are formed in steel.

In such cases it is generally observed that the transformation into the new phase cannot be described as a growth of nuclei steadily increasing in size, but that it consists of the formation of parallel and intersecting systems of more or less needle-shaped lamellæ, which, as transformation progresses, do not increase in size but merely in number, the resulting pattern showing the type of lamellar structure met with in martensitic steels and known as *Widmannstätten* texture in meteorites and many alloys[2].

The investigation of the emission pattern of zirconium in an 'electron microscope' of the type described elsewhere[3], showed that the same texture is exhibited by α-crystallites formed from the β-phase. This is clearly shown by the accompanying photographs corresponding to cathode temperatures of 1100° C., that is, well above the transition point, (865° C.) and 600° C., a temperature well below this point. It is interesting to see that the regions, originally occupied by the β-crystallites, can still be discriminated in the α-pattern by the difference in 'direction' of the lamellæ in the adjoining regions (needles of the α-modification of zirconium have already been observed in etched test pieces after suitable cooling from the β-state[4]).



β-Zr (1100° C.) α-Zr (600° C.) β-Zr (1150° C.)

EMISSION PATTERNS OF ZIRCONIUM ABOVE AND BELOW THE TRANSITION POINT (865° C.).*

On retransformation into the β-state, the original crystallites reappeared, as is evident from the photograph at 1150° C., which (apart from the left-hand side, where crystal growth has already started: see below) is practically identical with that at 1100° C. This behaviour, which is totally different from the phenomenon of crystal growth observed on transition of α into γ iron[5], seems to confirm the conclusion deduced from the X-ray investigation mentioned above.

It seems worth mentioning that at a cathode temperature above 1150° C. the β-crystallites showed phenomena of growth, whereby the capacity for growth of the individual crystallites could be influenced by the insertion of a temporary transition into the α-modification.

A detailed account of these observations will be published in *Physica*.

A Modified Phase Rule Equation

It is well known that the Gibbs Phase Rule as applied' to equilibrated macro-systems subject to changes of temperature, pressure and concentration may be written in the form

$$P + F = C + 2,$$

where P is the number of phases, F the number of degrees of freedom and C the number of components. In applying the equation to physical and chemical equilibrium, the number of components C is taken as the *minimum* number of independently variable constituents in terms of which the equilibrium may be expressed in the form of a chemical equation. The term 'number of components' has thus to bear the brunt of the matter and assume a responsibility not shouldered by the equation itself. In fact, it is frequently necessary to write out a properly balanced chemical equation in order to decide upon the number of components in the system. Moreover, the equation cannot be applied without making allowance for certain restrictions when the phases approach identity, as in critical phenomena, or when one of the substances is kept in a definite weight-ratio to some other substance in the system, as in dissociation phenomena.

In view of these difficulties it is perhaps desirable to state the Phase Rule in terms more readily comprehended by the ordinary chemist and metallurgist. If we retain the original definitions of phases and degrees of freedom and let C be the *total* number of chemical constituents (that is, actual chemical substances) present in the system we may write

$$P + F + R = C + 2 - r,$$

where R is the number of reversible chemical reactions occurring in the system, and r, the restriction term, is equal to the number of pairs of phases having the same concentration or composition. This equation may then be applied without reference to stoichiometric chemical equations and without recourse to any process of choosing components.

Thus in the thermal dissociation of calcium carbonate:

$$CaCO_3 \rightleftarrows CaO + CO_2,$$

we have three constituents and one reversible chemical reaction so that

$$3 + F + 1 = 3 + 2 - 0; \text{ that is, } F = 1.$$

Again, in the dissociation of ammonium chloride

$$NH_4Cl \rightleftarrows NH_3 + HCl,$$

we have a reversible chemical reaction and also one pair of phases (the solid phase and the gas phase) with identical composition, so that

$$2 + F + 1 = 3 + 2 - 1; \text{ that is, } F = 1.$$

The equation also leads to a clear differentiation between physical and chemical change in transition processes. We know, for example, that the system

$$Na_2SO_4 \cdot 10\,H_2O \rightleftarrows Na_2SO_4 + \text{liquid}$$

containing three substances (decahydrate, anhydrous salt and water) is invariant (that is, $F = 0$). Accordingly,

$$4 + 0 + R = 3 + 2 - 0 \text{ and } R = 1.$$

The point is thus an incongruent melting point arising from the rupture or formation of chemical linkages. A similar behaviour is exhibited by an intermetallic compound with a submerged maximum, as, for example,

$$AuSn_4 \rightleftarrows AuSn_2 + \text{liquid};$$

but in this case the linkages involved are metallic. These transition processes are conveniently termed *meritectic* reactions (from *meros*, part; *tectic*, melting) to distinguish them from the ordinary peritectic reactions of solid solutions. Applying the equation to a binary system of two solid solutions undergoing peritectic reaction,

$$\alpha \rightleftarrows \beta + \text{liquid},$$

we have

$$4 + 0 + R = 2 + 2 - 0; \text{ and } R = 0.$$

It is clear, therefore, that the peritectic transformation of solid solutions does not involve the rupture of chemical or metallic linkages.

The modified equation, while removing the bugbear of the term component, is also of utility in other directions and in my opinion is much more easy to apply than the customary equation.

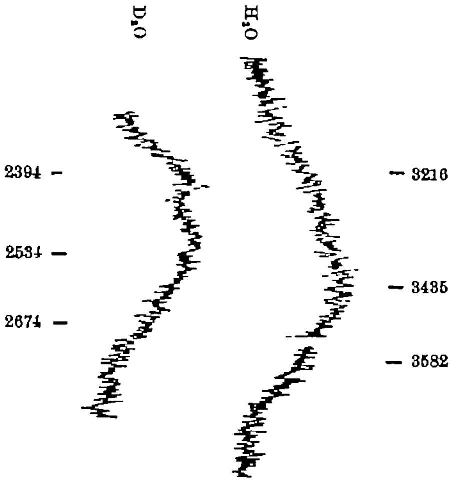
Constitution of Heavy Water

On lines similar to the investigation by one of us on ordinary water[1,2], we have studied the Raman band of heavy water (99·6 per cent D_2O) at different temperatures ranging from 6° to 100° C. Within this range, the principal band for this substance is very broad and diffuse, extending in its Raman frequencies from 2,254 to 2,784 cm⁻¹. It shows a structure similar to that of ordinary water, having at 30° C. three components merging into one another with their maxima at 2,394, 2,534 and 2,674 cm^{-1}. The one important characteristic of this band, as compared to that of ordinary water, which earlier workers with this substance[3,4,5] failed to record, is the difference in the relative intensities of the three components. The accompanying microphotometric curves of the bands for the two types of water were taken at 30° C. It is clear from the curves that for



heavy water, the marked components are better resolved, the first component with Raman frequency 2,394 being nearly of the same intensity as the second, whereas for ordinary water, the first component is not only not well resolved from the second, but is also less intense.

With the view of ascertaining the cause of this difference, the changes with temperature in the relative intensities of the three components for heavy water were investigated. The results revealed, in general, a similarity in the changes for the two kinds of water, but the structure of the band for heavy water at any temperature is analogous to that for ordinary water at a lower temperature. Owing to the extreme diffuseness of the bands, it is difficult to determine the exact values of the corresponding temperatures.

If these components are attributed to different polymers, namely, single, double and triple molecules[1], the difference in the relative intensities of the components for the two types of water at the same temperature indicates a difference in the relative proportions of their polymers. The similarity in the structure of the band for heavy water at any temperature to that of ordinary water at a lower temperature leads to the conclusion that characteristic temperatures for heavy water should be higher than for its isotopic analogue. This observation is confirmed from experiment, the temperatures of freezing, maximum density and boiling being 3·8°, 11·6° and 101·4° C. respectively.

For heavy water, the component with the smallest frequency at 2,394 cm^{-1}, which we attribute to $(D_2O)_3$, diminishes in intensity with increasing temperature, whereas the third component (2,674 cm^{-1}) increases correspondingly, the central component attributed to $(D_2O)_2$ remaining almost unaltered. These results indicate that the equilibrium between the polymers changes with temperature as for ordinary water.

Ethnographical Museums

RECENTLY, there has been a certain correspondence in the Press about the India Museum, and now the question has been ventilated in NATURE of January 29 (pp. 177, 193). Though, unfortunately, I have only the usual superficial knowledge of things Indian, may I discuss the wider point of view of archæology and ethnology in general ? These are, of course, one and the same, the latter being only the former in the present tense. This point is indeed made in the remark regretting "the present divorce of antiquity from historic times".

A museum is, or should be, a centre of teaching and study, where everyone should have facilities for acquiring knowledge and broadening his interests in mankind according to his ability. This, of course, means teaching for the serious student, and general information for the vaguely interested public.

Coming back to the particular case in point, we may notice that the purpose of the Victoria and Albert Museum, of which the India Museum is a section, is "to promote the application of art to manufactures". Yet I have noticed that it is Indian 'art' that is so much mentioned in the recent correspondence. Is all the emphasis once again to be laid on 'art' to the detriment of 'industry' ?

Alas, after literature, art has formed the greatest obstacle with which the new study of man's accomplishment has had to contend. All the world over, whether in ancient Egypt, in China, in the Muslim world, or in Europe, the approach to the past has always been primarily through an appreciation of the written word. Later has come an appreciation of the beautiful works of the past. It is only within the last fifty years or more that the new study of archæology and ethnology has grown up. That is a study of all the phenomena of any given civilization—not only of the things beautiful, but also of those that never aspired to beauty or sank into ugliness, but were merely made for everyday use.

The studies of literature and of art have been firmly entrenched in man's mind for many hundreds of years, and have produced their own splendid results. Hence, many find difficulty in discerning the new science. Then, if it begins to dawn upon them, they are liable to look upon it merely as an aberration of those who are not good enough to scale the heights of the others. It should, however, stand forth clearly as the independent line of study which it is, with its own methods and leading to its own results, just as do the other two.

Neither art nor literature is the whole of man's activities, but each is a part of them, just as much as the industries of flint-working, potting, weaving, carpentry, mechanics or any other.

Hence a museum should not be, as it used to be, a collection of things quaint or curious, or even of a few superlatively beautiful ones. It should, on the contrary, give a comprehensive view of a people's complete activities, good, bad and indifferent. These activities cannot be studied properly without reference to those of surrounding countries. Fortunately, an understanding of this has been growing recently. It is now many years since Sir Flinders Petrie began clamouring for a central institution which would cater for this sort of thing, and only last year a prize was offered for an essay treating of Egyptian archæology on these lines.

Finally, it may be remarked that an attractive display of objects will always appeal to people, whereas a learned treatise will only repel the majority.

Solubility of Cellulose in Water

PURE cellulose is generally regarded as being perfectly insoluble in water, but experiments recently carried out in this laboratory indicate that pure cellulose is slightly soluble in pure water.

High-grade bleached commercial grades of cellulose contain water-soluble impurities (both organic and inorganic), usually less than 1 per cent. This water-soluble extract is determined by digesting a weighed sample of the cellulose for 2 hours on a water-bath with twenty times its own weight of water and filtering off the extract. This operation is repeated another three times and the combined four filtrates are evaporated to dryness on the water-bath, the residue being weighed and calculated as the water-soluble content of the cellulose.

My own experiments show, however, that when this method of extraction is continued on the same sample, after the above determination of water soluble content, approximately constant weights of residue may be recovered from subsequent extracts in a long series of extractions.

Hydrolysis was suspected at this temperature of extraction (95–100° C.), and a further series of experiments were conducted with very pure distilled water at ordinary temperatures (15–18° C.) in carefully selected apparatus, when it was found that the extracts again gave a lower but still approximately constant residue after repeated extractions.

In one case a sample of cellulose, weighing 10 gm., after removal of water-soluble impurities, was digested and washed in the cold with 20 litres of distilled water, corresponding to fifty extractions, without diminution of the residue obtained from the last extract. Micro-biological attack of the cellulose was considered as a possible explanation, but after consideration of microscopical and other evidence, was discarded. The following are typical of the results obtained when using 20 gm. samples stirred in 800 c.c. water for 2 hours at 15–18° C.:

	Cellulose	Average Water-soluble Residue in Extracts
A.	Bleached spruce wood .. .. (sulphite process)	18·6 mgm. per litre
B.	„ „	21·0 „ „ „
C.	Alpha-Cellulose from B . ..	13·6 „ „ „
D.	Bleached cotton wool . .	20·6 „ „ „

The residue obtained from the extracts after evaporation, when final drying is done in a desiccator over phosphoric acid, appears as a white film, having a uniform granular appearance. Under the microscope, it is largely colloidal and isotropic but contains some scattered crystallites. The residue, if not charred during drying, is soluble in water and the solution shows a reducing action equivalent to about 15 per cent calculated as glucose. Whether this hydrolysis has taken place during extraction or evaporation of the extracts remains to be determined. Evaporation of a concentrated solution of the residue yielded a transparent brittle gum-like substance giving negative reactions for the presence of crystalline cellulose or of dextrin.

One fact appears certain, namely, that pure cellulose is slightly soluble in pure water at ordinary temperatures to the extent of 1·4 to 2·1 parts per 100,000, forming a perfectly clear sol. This dispersion of cellulose in water is probably accompanied by some breakdown in the cellulose molecule, but the nature of the reaction will take some time to determine.

This slight solubility of cellulose in water obviously sheds light on numerous scientific and technical problems involving the physical and chemical reactions of cellulose, from its origin in the cell-wall to its resolution by bacteria.

'Convergent' Sunbeams

THE phenomenon of 'divergent' beams of sunlight is known to everyone. The illusion of divergence of the beams is so good that one has forcibly to remind himself that they are really parallel.

One day last summer, I observed 'convergent' beams and this observation was corroborated by others with me. It was late afternoon in a flat country. Clouds hid the sun, which, perhaps, was nearly eclipsed by the horizon. It had been raining in the surrounding country and cumulus clouds were still prominent in the west. The rays of the setting sun gave the familiar fan-like pattern in the west, passed almost invisibly overhead and then 'converged' in the east as if they emanated from a sun on the eastern horizon. These rays were of lower intensity than those in the west but were plainly visible.

The explanation of the phenomenon is obvious; one is under the parallel beams, and looking along them in opposite directions. The spectacle was new to me.

Origin of Stellar Energy

IT is well known that matter consists of nuclei and electrons. Nevertheless it can be shown that in bodies of very large mass, this usual 'electronic' state of matter can become unstable. The reason for this lies in the fact that the 'electronic' state of matter does not lead to extremely great densities, because at such densities electrons form a Fermi gas having an immense pressure. On the other hand, it is easy to see that matter can go into another state which is much more compressible—the state where all the nuclei and electrons have combined to form neutrons.[1] Even if we assume that neutrons repel each other, this repulsion can become appreciable only at densities of the order of magnitude of nuclear densities, that is, 10^{14} gm./cm.^{3}, and the pressure of a Fermi gas consisting of neutrons is much less than that of an electronic gas of the same density, because of the greater mass of the neutrons.

Therefore, in spite of the fact that the 'neutronic' state of matter is, in usual conditions, energetically less favourable, since the reaction of neutron formation is strongly endothermic, this state must nevertheless become stable when the mass of the body is large enough. In this case, the gravitational energy gained in going over to the neutronic state with its greater density, compensates for the losses of internal energy.

It is easy to compute the critical mass of the body for which the 'neutronic' state begins to be more stable than the 'electronic' state. First of all we must calculate the energy necessary to form one neutron. For example, in the reaction ${}^{16}_{8}O + 8\epsilon^- = 16\,{}^{1}_{0}n$, we find from the mass defects that to form one neutron the energy required is 0·008 mass units or $1{\cdot}2\,10^{-5}$ ergs (7·5 Mv.). To transform one gram of matter into neutrons we thus need 7×10^{18} erg./gm.

Now we must calculate the gain in gravitational energy. The gravitational energy of the much less dense 'electronic' state can, of course, be neglected. Let us assume first of all that the neutronic state has a constant density, 10^{14} gm./cm.^{3}. The gravitational energy of a homogeneous sphere of mass M is then $3 \times 10^{-3}M^{5/3}$ ergs. For the stability of the neutronic phase we must then have $3\times10^{-3}M^{5/3} > 7\times10^{18}M$, or, $M>10^{32}$ gm.$=0{\cdot}05 \bigcirc$, where $\bigcirc$ is the mass of the sun. On the other hand, if we assume that the neutrons behave like a Fermi gas, we find for the energy $7\times10^{-22}M^{7/3}$ ergs and hence

$$M > 1{\cdot}5\times10^{30} = 10^{-3} \bigcirc$$

which critical value is even less than on the first assumption.

When the mass of the body is greater than the critical mass, then in the formation of the 'neutronic' phase an enormous amount of energy is liberated, and we see that the conception of a 'neutronic' state of matter gives an immediate answer to the question of the sources of stellar energy. The sun during its probable time of radiation (about 2×10^9 years according to general relativity theory) must have emitted something of the order of magnitude of 3×10^{50} ergs. The liberation of this amount of energy requires the transition of only about 2 per cent of the mass of the sun (with the assumption of constant density) or even only $3 \times 10^{-3} \bigcirc$ (with the Fermi gas model) to the 'neutronic' phase. Even for such a bright star as β Orionis, we find for the mass of the neutronic core only about $0{\cdot}1 \bigcirc$ (with the Fermi gas model).

Thus we can regard a star as a body which has a neutronic core the steady growth of which liberates the energy which maintains the star at its high temperature; the condition at the boundary between the two phases is as usual the equality of chemical potentials. The detailed investigation of such a model should make possible the construction of a consistent theory of stars.

As regards the question of how the initial core is formed, I have already shown[2] that the formation of a core must certainly take place in a body with a mass greater than $1{\cdot}5 \odot$. In stars with smaller mass the conditions which make the formation of the initial core possible have yet to be made clear.

Points from Foregoing Letters

CONTRARY to expectations, γ-rays of 17 million volts energy eject neutrons from the nuclei of some of the heavier elements only. Prof. Niels Bohr suggests that this selective behaviour is conditioned by "certain special vibratory motions with singular radiation properties" and these, together with other possible modes of vibration, lead to an energy distribution analogous to that of the heat motions in a solid body at a low temperature. The radiative properties of the nucleus in this state will resemble that of a black body with a temperature of several million volts. Based on this analogy Prof. Bohr gives a formula of selective absorption, relating the cross-section for nuclear photo-effects with the frequency of the incident γ-rays and the probabilities for the re-emission of a quantum.

Prof. Max Born proposes a 'principle of reciprocity' according to which each general law in x-space (space-time dimensions) has an 'inverse image' in the p-space (of momenta and energy). He indicates some of the consequences and numerical results: An energetically closed system would correspond to a closed momentum-space, with a radius c representing the maximum possible momentum. A number of quantities which are infinite in accepted theories become finite. Coulomb's law is modified, which implies a change in Rutherford's law of scattering so that for head-on collisions there is an absolute limit for the distance of closest approach. Plank's and Stephan-Boltzmann's laws and the laws of the kinetic theory of gases are altered. Applied to the theory of nuclear structure, the new principle yields, for the mean kinetic energy per nuclear particle and for the ratio between the nuclear and electronic radii, values in excellent agreement with Bethe's estimates.

Wilson chamber photographs showing the emission of the electron from atoms when they interact with neutrons are submitted by S. Kikuchi and H. Aoki. The authors assume the expulsion of an orbital electron or an electron in a negative state, due to some unknown interaction between the electron and heavy particle.

According to Dr. J. W. Weyssenhoff, from the simple classical theory it follows that, in particular cases, the superimposed action of a magnetic dipole can annihilate the radiation of an electric charge in motion. This may remove the difficulty in connexion with Mathisson's theory of the spinning electron since the moving electron charge will be compensated so that there is no radiation.

In a paramagnetic salt it should be possible, according to Prof. K. S. Krishnan and A. Bose, from measurements on the magnetic anisotropy of the crystal at different temperatures, to calculate the coupling between the orbital and the spin angular momenta of the paramagnetic ion. The value of the coupling in Ni^{++} calculated in this manner agrees well with the spectroscopic value.

Photographs of electron-emission patterns of α-zirconium (at 600° C., cathode temperature) and of β-zirconium (at 1100° C.) submitted by Dr. W. G. Burgers and J. J. A. Ploos van Amstel show that, as in the case of martensite, a *Widmannstätten* texture is exhibited by α-crystallites formed from the β-phase. On retransformation into the β-state, the original crystallites reappear, showing phenomena of growth.

The difficulties associated with the application of the Gibbs Phase Rule equation arise from the special significance which is attached to the term component. A modified equation proposed by Dr. S. T. Bowden avoids the use of this term and leads to a clear differentiation between the phase transformations of compounds and solid solutions.

Pure cellulose is generally regarded as being perfectly insoluble in water, but from investigations described by James Strachan, it appears that high-grade cellulose from wood and from cotton is slightly soluble in pure water at 15–18° C. to the extent of 1·4 to 2·1 parts per 100,000, and that this dispersion of cellulose in water is probably accompanied by some breakdown in the cellulose molecule.

Research Items

Ancient Man in Devon

THE implementiferous gravels at Broome, Dorset (the gravels in question are actually over the county boundary in Devon), have long been famous. Chert implements were discovered there in 1877–78. Mr. Reid Moir has now investigated these gravels and the contained implements in the light of the knowledge of quaternary deposits and 'palæolithic' implements which has accrued since the gravels and implements were originally described (*Devon Archæol. Exploration Soc.*, 2; 1937). The gravels were regarded in earlier investigations as laid down by normal river action; but it cannot be questioned that, during the Ice Age, Devon, so near the main terrain of the glaciers, must have been affected by the tremendous happenings of the period. The deposits must therefore be regarded as laid down by an abnormal flow due to the melting ice. It would appear that some twenty feet of the deposit was laid down as a result of the passing away of glacial conditions. Then comes about four feet of comparative quiescence, in which palæolithic hunters may have lived on the river bank. Another period of very active deposition follows in which the uppermost thirty feet of gravels was laid down. This is only vaguely stratified, or 'tumbled'. The archæological evidence fits in with this hypothesis. The specimens from these deposits can be classified as (*a*) primitive, possibly eolithic, implements, much rolled and abraded; (*b*) one or two early Acheulean hand-axes showing signs of transport; (*c*) Late Acheulean hand-axes, fine and unabraded; (*d*) Clacton III material unabraded; (*e*) some Levallois flakes, but not a definite Levallois industry. There can be no doubt that the middle layer was laid down in Late Acheulean and Clacton III (High Lodge) times. The Broome deposits fall in line with the 100-ft. terrace of the Lower Thames Valley, Derby Rd., Ipswich, and Hoxne, Suffolk. The lower deposit of Broome, therefore, is connected with the glaciation of the Kimmeridge Chalky Boulder Clay and the uppermost with the Upper Chalky Boulder Clay; while there is strong evidence for correlating the upper gravels with the deposit of 'clay with flints' of East Devon on the Bere–Seaton Road, a site which Mr. Reid Moir also discusses.

Mesolithic Flints from West Hartlepool

Finds of worked flints from the submerged forest at West Hartlepool, which have the appearance of an early stage of the Maglemose culture, or possibly even more primitive and suggestive of that of Duvense, Lubeck, have been recorded by Dr. C. T. Trechmann, Mr. A. S. Kennard adding a note on the Mollusca (*Proc. Prehist. Soc.*, July–Dec. 1936). The submerged forest is situated between Hartlepool and West Hartlepool and along the coast southward to Seaton Carew. The main portion occupies a depression between two outcrops of magnesian limestone. A mammoth tusk, antlers of red deer and Irish elk, and other mammalian remains have been found beneath the deposit. A rough but well-chipped pick-like flint implement, now in the Sunderland Museum, was found "on the turf of the buried forest" at Seaton Carew in 1860. In 1934–35, flint flakes and chippings and a fresh shell of *Littorina littorea* were found at West Hartlepool near the base of the peat, while a patch six feet long and three feet wide yielded a quantity of very sharp implements and chippings of very black flint with white chalky patches and streaks. These appear to be the work of one person thrown down together. The fifty specimens, all found at the junction of the underlying blue clay with the peat, included a number of elongated micro flakes, a microlith blunted down one edge, a micro-burin and a broken, asymmetrically notched flake, probably a microlith in process of manufacture. In the peat itself are found indefinitely chipped flints of an elongated shape, not easy to comprehend, but in certain characters recalling the pick in the Sunderland Museum. It seems possible that two periods are represented, one at the base and the other higher up in the peat. The peat is very compressed and contains birch, hazel, *Equisetum*, iris, etc. Permeation by drain refuse makes pollen analysis unsatisfactory. The period is early Littorina or Atlantic. The worked flints are of Maglemose type, and a comparison with other sites of the submerged forest regions of the Yorkshire, Durham and Northumberland coasts suggests that the worked flints found at Skipsea are of like appearance.

Inactivation of Adenosine by Blood

ALL tissues of the body contain in greater or less amounts adenosine or allied compounds, substances which, when they enter the blood-stream, have far-reaching physiological effects. The existence of enzyme systems in the tissues capable of inactivating these substances has been known for some time, but up to the present no such enzymes in the blood have been described. Drury, Lutwak-Mann and Solandt (*Quart. J. Exp. Physiol.*, 27, 215; 1938) have now demonstrated the presence in the blood plasma of the ordinary laboratory animals and of man of an enzyme inactivating adenosine, probably by deaminating it to form the biologically inert substance inosine. Cat's plasma is by far the most active, 0·1 mgm. of adenosine being destroyed in so short a time as 2 min. by 1 c.cm. of plasma. This very high degree of activity is, however, exceptional and is only reached on account of the remarkable fact that the activity of the plasma of anæsthetized animals gradually increases during an experiment, until 5–6 hours after the beginning of an experiment it may be 12 times the normal value. Although this increase appears to be accelerated by a fall of blood pressure, the authors are unable to correlate it directly with this, and it appears to be unconnected with the presence of any particular organ. The authors suggest that the increase in enzyme activity may be due to the formation of more enzyme from inactive plasma protein.

Larvæ and Pupæ of Aquatic Diptera

MEMOIR 205 (1937) of the Cornell University Agricultural Station is written by Prof. O. A. Johannsen and forms Part 3 of a series entitled "Aquatic Diptera". In the present case, the single family Chironomidæ is dealt with and, in particular, four out of five of its sub-families. The Chironominæ are the family left out to be dealt with in a subsequent memoir. While this work deals primarily with North American genera and species, the keys include European forms in some cases where it is considered desirable to direct attention to differential characters. The work is illustrated by eight plates containing more than 270 line figures. Since practically all the European genera are figured, the work will prove a valuable aid to the identification of forms found on both sides of the Atlantic Ocean. The material which forms the basis of the study was collected and reared by the author and some of it a number of years ago. Parts IV and V, which conclude the series, it is mentioned, have been completed and will appear as another memoir within a short time. When completed, the work will form an admirable and up-to-date guide to the study of the many forms of Diptera found in aquatic habitats.

Crustacea of the Philippines

A CHECK list of Philippine Island decapods is given by P. Estampador Eulogio (*Philippine J. Sci.*, 62, No. 4; 1937), but there are many additions to the fauna recently described from Woltereck's Wallacea Expedition to the Philippine and adjacent islands. The contributions already published are summarized by Dr. Woltereck in Band 34, Heft 3/5 of the Internationale Revue der gesamten Hydrobiologie und Hydrographie, 1937. This number is devoted to the Wallacea Expedition, and includes original contributions, especially on the freshwater Crustacea, by H. Balss (Potamonid crabs), V. Brehm (Diaptomids), W. L. Tressler (Ostracods) and E. Woltereck (freshwater Caridea). The Potamonid crabs are common in this region, living much on land and having no free-swimming larvæ. Dr. Woltereck has two important and extensive papers, the first dealing with races and species of the genus *Caridina* present in the islands, the second with their systematics and geographical distribution. The latter includes a list of all known species and a comparison with other Atyidæ.

Researches on Copepods

DR. C. H. EDMONDSON has studied copepods in Hawaii, Fiji and Tahiti (Quantitative Studies of Copepods in Hawaii with Brief Surveys in Fiji and Tahiti; Occasional Papers of Bernice P. Bishop Museum, Honolulu, Hawaii, 13, No. 12, 1937). The semi-enclosed bodies of water are shown to support a much larger number of copepods than do the open reefs and a large number of animals feed upon the copepods. The author describes the feeding habits of *Eleutheria*, or creeping medusa, abundant among *Ulva* and other seaweeds on the shores of Oahu. "These minute medusæ may be seen ingesting copepods as large as themselves, becoming greatly distorted in the process, and at the same time holding two or three other copepods within the grasp of their tentacles." It is found that shoal water copepods are more resistant to falling than to rising temperatures. A large proportion survive 5° C. for 17 hours, but all die in 16½ hours at 35° C. Dilute sea water in the proportion of 1 part sea water to 3 parts fresh water has no detrimental effect on copepods during a period of 48 hours. Many copepods survive a reduction in pH from 8·6 to 5·8 for 24 hours, a few for 48 hours, none for 72 hours. Adult specimens are more sensitive than larval forms to altered ecological conditions.

Lichens from Greenland

THE lichens collected by Prof. Theodor M. Fries (largely crustaceous) in 1871, supplemented by the collections of Dr. Johannes Grøntved (mainly macro Lichenes) and others have been examined and collected into one volume by B. Lynge of Oslo. This volume must represent a very comprehensive survey of present-day knowledge of Greenland lichens, especially of the region of and around the Island of Disko. This region was visited primarily by the 1871 expedition to bring to Sweden some blocks of iron, detected the previous year by A. E. Nordenskiöld; these were formerly thought to be of meteoric origin, but were later proved to be telluric. (Meddelelser om Grønland. Bd. 118. No. 8. 1937.) The collections of Fries, gathered under the forced conditions of an Arctic expedition, were found to be in remarkably good preservation, though some difficulties were experienced with regard to dates and exact localities. Many of the lichens were difficult to photograph, and a method, new to lichenology, was used to throw the surface details into sharper relief. The lichen is suffused with the vapours of a white and very fine-grained ammonium salt. Temporarily the colour contrasts of disk and thallus are masked, but afterwards the covering salt evaporates and no damage is done to the plant. Use was also made of Prof. Asahina's new reagent paraphenylenediamin, which in many genera was found to be of great value for specific distinctions.

Peculiar Cystoliths in the Cucurbitaceæ

DR. H. L. CHAKRAVARTY's paper upon the physiological anatomy of the leaves of Cucurbitaceæ (*Philippine J. Sci.*, 63, No. 4, August 1937) seems to require a revision of the accepted ideas of those peculiar aggregates of calcium carbonate known usually as cystoliths. In the genus *Momordica*, and particularly in *M. cochinchinensis*, such irregular deposits of calcium carbonate are very common in enormously enlarged epidermal cells. In *M. charantia* the cellulose peg upon which the deposits are formed is very short, but in *M. cochinchinensis* the cystoliths have no definite structure. They are very irregularly branched, and the calcium carbonate strongly impregnates a stratified, branched cellulose skeleton. Their frequency is remarkable—in a square centimetre of leaf 1,000–1,600; in an entire leaf there may be as many as 100,000; so that enormous quantities of calcium carbonate must be accumulated in a single plant. The author directs attention to the fact that Zimmerman has described a similar type of cystolith in *M. rostrata* Zimmerman.

Endophytic Fungi of Rye-Grass

A FUNGUS which has hitherto defied identification is commonly distributed freely throughout most tissues of rye-grass, *Lolium perenne*. It has sometimes been regarded as a stage in the life-history of *Epichloe typhina*, but Miss Kathleen Sampson shows, in a recent paper (*Trans. Brit. Mycol. Soc.*, 21, Pts. 1 and 2, 84, Oct. 1937), that it has few characters in common with this fungus. The endophyte has been isolated upon egg medium, and cultured afterwards upon agar media, but no further clue to its identity has thereby been revealed. A second fungus has been isolated, which grows readily upon many kinds of media, and which is no less systemic than the first. It produces spiral hyphæ and microconidia, but provides no reliable diagnostic features.

Crustal Deformations around Lake Biwa

LAKE BIWA is the largest lake in Japan, its length from north to south being thirty-seven miles, and its average width nine miles. Along its shoreline are distributed no fewer than thirty-six water-gauges, and, from their records, Prof. C. Tsuboi (*Earthq. Res. Inst. Bull.*, 15, 935–942; 1937) has calculated the mean annual height of the surface at each station from 1887 until 1929. While there are many fluctuations in level, due probably to variations of rainfall, the mean annual height at all the stations shows that the level is falling at the rate of 5 ft. per century, and it is interesting to note that well-developed terraces occur at a height of about 650 ft. above the present surface. At one of the stations at the south end of the lake, the curve of mean annual height indicates a fall in level of about 6 in. during the years mentioned; while at another at the north end there was a rise of about the same amount. This suggests that the crust around the lake has been tilted towards the north by about 0·7 second of arc, and repeated series of levels along both sides of the lake agree nearly with this estimate.

Effects of Intensive Drying

SINCE H. B. Baker from 1912 reported rises in boiling point, surface tension and freezing point in the case of liquids intensively dried by phosphorus pentoxide, the problem has been investigated by others, who have mostly either failed to observe any change in physical properties or have explained the effects as due to superheating. D. A. Lacoss and A. W. C. Menzies (*J. Amer. Chem. Soc.*, 59, 2676; 1937) now find that when purified benzene is desiccated with purified phosphorus pentoxide with precautions to exclude or destroy dust, its vapour pressure, near 80°, is lowered markedly if the drying process is carried on at room temperature, but raised slightly if the drying is carried on at 90° or 105°. Without opening the sealed apparatus, the vapour pressure could be caused to revert to the normal value by heating the liquid out of contact with the phosphorus pentoxide, provided the desiccation had not been too vigorous. On allowing access of normal air, vapour pressures likewise reverted to the normal value. No change in vapour pressure was found in the case of benzene if the materials used were not both purified and also dust-free, nor when barium oxide or magnesium perchlorate were used as desiccants. Carbon tetrachloride, normal heptane and cyclohexane failed to show any change of vapour pressure upon desiccation under the same conditions as had given positive results with benzene.

Raman Effect and Analysis

AN interesting review of the application of the Raman effect to the analysis of organic mixtures by J. Goubeau appears in a recent issue of *Angewandte Chemie* (51, 11; 1938). The author points out the suitability of the method for the analysis of substances with non-polar linkages, and most organic substances fall into this class. The spectrum being determined by the actual structure of the molecule is capable of distinguishing between all types of structural isomerides. Optical isomerides and their racemates give the same spectrum. The application of the Raman spectrum to qualitative analysis is discussed, and the sensitivity of the method is considered. The applications of the method to typical analytical problems are then mentioned. The process has been used to detect impurities in substances, for example, the presence of secondary butyl alcohol in fermentation propyl alcohol, methyl bromide in ethyl bromide, and methyl alcohol in ethyl alcohol. The identification of substances by this method has the advantage over the determination of melting point or boiling point that the substance is not affected by the process. The existence of characteristic lines for different groups of atoms (C : C, C ⋮ C, C : O, etc.) makes it possible to classify a substance. The use of the method when dealing with mixtures of substances difficult to identify in other ways is described, the work of Dupont on the terpenes being mentioned. *Cis*- and *trans*-isoeugenol have been detected in the presence of each other. Mixtures of hydrocarbons have also been investigated. Quantitative analysis is also possible by determining the intensities of characteristic lines of the substance.

Reduction of Occultations for Faint Stars

In a recently published paper (*J. Brit. Astro. Assoc.*, 48, 3, January 1938) by Dr. M. Davidson an entirely new method is developed for the reduction of occultations. Instead of using the ordinary Besselian geometry, Dr. Davidson employs rectangular equatorial co-ordinates and shows how very accurate results are attainable. The method is applicable to stars of all magnitudes, but as the Nautical Almanac Office has computed certain constants for occultation stars brighter than magnitude 7·5, it is not suggested that the method should be used for these. The author hints at the possibility of taking into consideration the inequalities of the limb of the moon, thus greatly enhancing the value of a single occultation, and shows how this might be done, but admits the great difficulties in the practical application.

Interpretation of ε Aurigæ

THE paper on ε Aurigæ by Kuiper, Struve, and Strömgren, referred to in NATURE of January 22, p. 154, is now published (*Astrophys. J.*, 86, 570), giving full details of the latest theory regarding this most interesting binary star. The following is a short summary of the system as postulated by the authors: The principal component, the so-called 'infra-red star' (*I* star), has a temperature of only 1,200°–1,400° and contributes no appreciable light in the spectral region covered by the observations. It has a very great diameter (about one third of the major diameter of the orbit) so that the outer layers of its atmosphere are as near to the second component as to the centre of the *I* star itself, and are subject to greater influence from this source. This second component, an *F2* star of much smaller diameter, is the source of the observed spectrum as well as of the visible light from the system, and by photoelectric action of its ultra-violet radiation produces a shell of highly ionized material in the outermost layers of the *I* star. This shell is semi-transparent, and during the eclipse of the *F2* star (which is of 'grazing' character, not central) absorbs about half the light of the latter in a non-selective manner, thus explaining the observed constant minimum of the light curve and the similarity of the spectrum throughout. In the words of one of the authors, we are presented with "a new astronomical phenomenon, an eclipse by a stellar Heaviside layer".

Science in India*

PROGRESS OF ZOOLOGY

Zoology and its advancement in India were chosen by Prof. G. Matthai as the subject of his presidential address before the Section of Zoology. The address dealt with the progress of zoology since the foundation of the Indian Science Congress in 1914, and more particularly with advances made since 1921.

Oceanographical investigation of the Indian Ocean has been conducted, since the first meeting of the Indian Science Congress, mainly by R.I.M.S. *Investigator* (until 1926) and the John Murray Expedition (1933–34), under the direction of Lieut.-Colonel Seymour Sewell. Previously the *Sealark* Expedition, under the leadership of Prof. J. Stanley Gardiner, had surveyed the western Indian Ocean south of the Maldives, more particularly the islands of the Chagos Archipelago and the Mascarene region (during 1905–6 and 1908–9). The work of the *Sealark* Expedition was mainly on problems relating to coral reefs and atolls and their biology, and was a continuation of a previous study of the Maldives and Laccadives. The R.I.M.S. *Investigator* concentrated its work in the Andaman Sea and the Bay of Bengal. The recent work of the John Murray Expedition was in the region of the Arabian Sea not covered by the *Sealark* Expedition. The study of the deep-sea biology of this region was assisted by physical, chemical, hydrographic and topographic investigations. The Survey of India collaborated with the John Murray Expedition in the cruise down the Maldives for making pendulum observations with the view of determining the nature of the foundations on which the Maldives and Laccadives are situated.

The work of the R.I.M.S. *Investigator* has extended our knowledge in regard to variation in the air temperature over the open waters of the Indian seas, in the wind force, in the amount of rainfall and in the relationship between the temperature of the sea surface and that of the air. There is always a vertical circulation of the layers of water caused largely by differences in temperature and salinity. A reversal of seasons is noticeable in the Indian seas at a depth of about 100 fathoms, comparable to the phenomenon that takes place in the temperate seas.

The 'Murray Ridge' discovered by the John Murray Expedition appears to be ultimately connected with the Carlsberg Ridge. The latter ridge divides the western region of the Indian Ocean into north-eastern and south-western halves. 'King Fuad Bank' is probably a submerged atoll with a distinct rim about 40 ft. high and a level floor 130 fathoms deep.

Regarding the reefs of the Western Indian Ocean, Prof. J. Stanley Gardiner recently pointed out that the Mascarene Region differs from the Chagos Archipelago in regard to conditions of reef-growth, changes adverse to reef-growth taking place at a much higher rate than in the latter. The regression of coral reefs in the Mascarene region does not appear to be due to any biological reason such as sedentary organisms that cause destruction by boring into the reefs, since the activity of such organisms is decreased at the depths at which reefs of this region are situated, or by sediment, which cannot settle on the seaward sides of reefs and banks, or by precipitation of calcium carbonate (for such precipitation is not visible on coral polyps on the seaward sides), or by currents the action of which is less on the sides facing the sea, or by temperature, which at 50 fathoms is not lower than 61·9° F., or by any decrease in the amount of plankton that serve as food material to coral polyps, for it is not liable to much quantitative variation in the Indian Ocean; nor does the chemical composition of the surface water in the Indian seas show any appreciable difference. The comparative poverty of the deep sea fauna in the Chagos and Mascarene regions is perhaps due to the hardness of the sea floor and to the fact that the quantity of plankton which serves as food material to the larger organisms is less in the Indian seas than in the temperate regions. In spite of the "shallow and fierce conditions" of life on the reefs of these regions, it is interesting to observe that the animals do not exhibit any special structural features that may be regarded as adaptations to the peculiar environmental conditions.

The madreporarian corals collected by Prof. J. Stanley Gardiner in his several expeditions to the Indian Ocean, particularly of the astraeid corals, provided material for a comparative study, of the morphological organization of their hard and soft parts, with the view of determining, if possible, the limits of species and genera, most previous taxonomic studies on corals having been based on characters taken solely from the hard parts that are liable to considerable variation. The same material, along with others, formed the basis for a study of colony-formation in astraeid corals.

The Zoological Survey of India has been engaged mainly in faunistic investigation, more especially of the brackish water of the Chilka Lake and its island (Barkuda), the estuarine fauna of Goa, the fauna of the Mutlah River, of the Inle Lake, the Indian freshwater molluscs and their trematode parasites, the aquatic and terrestrial fauna of the Punjab Salt Range, the cave fauna of the Siju Cave in Assam. Particular attention has been paid to the study of the fishes of hill streams in various parts of India and their structural and other adaptations to this peculiar environment. Fisheries research, especially on *Trochus*, has been conducted in the Andamans.

The address ends with a brief account of the research work carried out in the various zoology departments in India.

ENTOMOLOGY IN INDIA

The past, present and future of entomology in India formed the subject of Mr. M. Afzal Husain's presidential address to the Section of Entomology.

Linnæus (1758) included in his "Systema Naturæ" twelve species of Indian insects, and thirty years later Fabricius (1792–98) included in his "Entomologia systematica" one thousand Indian species, collected mostly by the Christian missionaries. During the last hundred and fifty years insects have received much attention. The number of the existing species of insects in India cannot be less than 2·5 millions, but only one in sixty is known. The

---

* *Continued from page* 297.

condition of Indian insect collections is also very unsatisfactory. It is distressing to find that most of the 'types' of Indian insects have gone out of the country. In the museums there is scarcely one 'type' for every hundred species described.

The Indian Museum laid the foundation of agricultural entomology in 1884 and the Imperial Institute of Agricultural Research at Pusa and the Agricultural Departments in the provinces and some Indian States have carried on the work. The Indian Central Cotton Committee, the Imperial Council of Agricultural Research, the Indian Tea Association and the Indian Lac Association have fostered the study of the insects of agricultural importance. Similarly, the small band of workers in forest entomology have achieved much success.

Ronald Ross and the workers who followed him made most valuable contributions to medical entomology, which have been of utmost utility to humanity. The Indian Research Fund Association has financed much research on insects of medical importance. Veterinary entomology has been greatly ignored, and it is only lately that an entomologist has been appointed to study insect pests of domesticated animals. In education, entomology has long been the Cinderella among sciences. Even in agricultural colleges it is only within the last few years that entomological teaching has received some attention. In most medical and veterinary colleges, entomology has no place in the curricula.

India is equally behind in entomological literature. There is no literature on insects in any of the vernaculars of India. The "Fauna of British India" is not developing as fast as one would wish it to develop. There are few catalogues of insect groups.

According to Sir Thomas Holland, among the sciences of economic value entomology perhaps ranks first in importance to India. Sir Mirza Ismail has drawn a very gloomy picture of the conditions in India. More than one hundred million people suffer from malaria every year and more than one million succumb to its effects. "The debility, poverty and apathy caused by this disease are factors of magnitude in retarding the national, social and economic progress of the country". *Anopheles* brought about the decay of the Greek and Roman civilizations, and is to-day one of the major obstacles to progress in India. According to Fletcher, the sugar-cane pests alone cause an annual loss of 300,000,000 rupees. The hide industry of India suffers a yearly loss of 1·5 crores of rupees from one insect—ox warble fly. At a very modest computation, the annual loss caused to India by insects has been put at 200 crores of rupees, and a loss of more than a million and a half of human lives. It is a truism that insects have been responsible for more destruction of property and loss of life than that caused by all the wars, floods, earthquakes, fires and famines in human history, and the losses caused by them are on the increase. Advancing civilization is producing conditions most suitable for insect multiplication and spread.

The tribute of Rs. 200 crores which India pays to the demons *Satpada* is a heavy drain, which should not be permitted to continue. An effective defence against these enemies will reduce this enormous wastage, and India will have enough money for her national development. To effect this, an army of workers must be produced to study insect life in all its aspects, and an army well equipped with knowledge and machinery to fight these demons. The public must be made to appreciate the importance of insect study. Entomology must take its place in the schools and universities, agricultural, medical and veterinary colleges. Funds should be provided to develop pure and applied entomology. India has depended far too long on the generous assistance of foreign workers and institutions for the progress of Indian entomology, but the time has come when she must shoulder her own burden. In every province and every State, insect surveys should be conducted, museums for insect collections and insect study established, Indian universities should come forward to take their full share in entomological development. An Entomological Society of India and an entomological journal are also needed.

RACIAL COMPOSITION OF THE HINDUKUSH TRIBES

DR. B. S. Guha in his presidential address to the Anthropological Section discussed the racial composition of the Hindukush tribes.

The region south of the Hindukush and Karakorum Mountains occupies a strategic position in the racial geography of India, for in these difficult, high mountainous valleys are still sheltered some of the remnants of the northern steppe folk who invaded India in the second millennium B.C.

Linguistically the tribes living in this area can be classified under two heads, namely, Dardic and Burushaski, with Kaffiri occupying an intermediate position between Iranian and Indian. Burushaski is unrelated to any known language; but Morgenstierne's investigations have shown the essentially Indian character of the Dardic and even the Kaffiri languages.

The earliest investigations on the somatic characters of these interesting tribes were those of Ujfalvy, followed by Stein, Dainelli and B. S. Guha, who, as a member of the scientific expedition sent by the Government of India, visited Kaffristan and Chitral in 1929.

From a careful consideration of physical characters, it appears that the basic racial type in the entire region is a short, dark dolichocephalic strain with prominent long nose, often aquiline, which might be regarded as a variant of Eugen Fischer's *Oriental race* and the most characteristic type of the region.

Besides this principal type, there is the southern extension of a broad-headed race closely allied to what is known as the *Dinaric race* of eastern Europe. In its strongest form it is found among the Khos of the Chitral valley and the Burushos of Hunza Nagir, though it occurs throughout the Dardic tribes in varying degrees. The skin colour in this race is prevailingly of a rosy white tint, but the eyes are more often hazel and green, and the colour of the hair is brown.

The third main racial strain is a tall dolichocephalic type with long and straight nose. It forms a very important layer among the Kaffir and the upper stratum of the Burusho and the Dardic tribes. The distribution of the cephalic index in this type follows the same trend as found by Ariens Kappers in the races of the Aral Caspian regions and very similar to that which forms the dominant element in the northern European population, from whom its chief distinction lies in the integumentary colours. Whereas in Sweden the blond type represents 49 per cent of the population, among the Kaffirs it does not exceed 15 per cent. Blondness, as is well known, is due to a deficiency mutation which suppresses the appearance of pigment. It is certain that this deficiency mutation has occurred in this and at least in another, namely, the *East-Baltic race*, at some time or other. It is probable that the mutations for skin, hair and eye colours have taken place separately. In the Baltic tribes, the high rate of the deficiency mutation might probably account for the larger percentage of the blond as compared to the Hindukush tribes, among whom the activators are perhaps dominant over suppression, causing the general persistence of the more pigmented people.

Lastly, an intruding Mongoloid element must also be responsible for the yellowish tint in the skin colour and broad flat nose found among many individuals.

The proportions of these strains vary in different parts. The Dinaric and the Proto-Nordic elements are stronger in the western valleys, whereas the basic Oriental and the Mongoloid elements are more conspicuous in the eastern valleys of the Upper Indus.

Breeding Investigations in the Sugar-Cane

Hybridization in and with the genus *Saccharum* formed the topic of Rao Bahadur T. S. Venkatraman's presidential address to the Section of Agriculture. Hybridization in the sugar-cane at the Imperial Sugar-cane Station at Coimbatore represents the first attempt to improve the subtropical types of canes. This genetical work, which has been going on at the Station for more than twenty-five years, has involved six species of *Saccharum* and four genera. There appear to be two distinct groups of wild species of *Saccharum*, both of which are confined to south-east Asia. Some of the wild species show wide variations. For example, a survey of the Indian wild species, *S. spontaneum*, showed a variation in sugar content of the juice from 0·5 per cent to 17·0 per cent, the latter figure being higher than that of certain cultivated Indian canes.

The Indian canes belonging to the species *S. barberi* are cultivated in subtropical India, though some are found farther south. Certain Indian canes cannot be ascribed to the genus *Saccharum*, the most important being the Mungo group of Dr. Barber.

A wide range of forms is known to arise from sugar-cane seed. This is explained by the heterozygous nature of the parents and the fact that most sugar-canes in cultivation are polyploid; for example, *S. offinarum* is octoploid.

Very little in-breeding has taken place in the sugar-cane, but much work has been done on inter-varietal, inter-specific and even inter-generic hybridization. Inter-varietal hybridization has been confined mostly to *S. officinarum*. At Coimbatore, economically important inter-specific hybrids have been obtained from *S. officinarum* × *S. spontaneum*. In Australia and Hawaii, *S. robustum* is being used for producing hardier seedlings for tropical regions.

At Coimbatore, inter-generic hybridization has been carried out, using such genera as *Sorghum* and *Bambusa*. The *Sorghum* cross was introduced to produce a shorter life-cycle which in the sugar-cane is from twelve to even twenty-four months. Hybrids producing a crop in seven months have been produced, and these have had high quality juices. Growth vigour in these, however, has proved disappointing. Crossing with the bamboo (*Bambusa*) has been introduced in order to obtain greater vigour, but experimental work has not proceeded far enough yet to justify definite conclusions, from the economic point of view.

The previously mentioned inter-generic hybrids have shown some interesting phenomena with regard to the manner in which the characters are shown in the F_1 generation and transmitted in further back-crosses with either parent. In both the *Sorghum* and *Bambusa* hybrids with sugar-cane, the one fact that stands out prominently is the general dominance of *Saccharum* characters in the F_1 generation.

In the case of *Saccharum* × *Sorghum* hybrids, the general dominance of *Saccharum* characters was found to persist even after twice back-crossing the hybrids with their *Sorghum* parent. Certain of the *Sorghum* hybrids exhibited morphological characters not found in either parent. Most of these hybrids were infertile in their first generation. On further vegetative propagation, however, some of them are showing an increasing fertility in the sexual organs with the result that, whereas in the earlier years no seeds could be obtained from these, it has since been possible to raise seedlings in large numbers from some of them and also to back-cross them with the two parents.

[*To be continued.*]

The Prehistoric People of Palestine*

By Sir Arthur Keith, F.R.S.

THE fossil remains of the earliest inhabitants of Palestine were discovered in caves of Mount Carmel by an expedition led by Miss Dorothy Garrod, and financed by two societies—the British School of Archæology in Jerusalem and the American School of Prehistoric Research. The early Palestinians were quite unlike any people now living, but are of profound interest, because, if not our actual ancestors, they are certainly near akin to the human stock which in the course of time gave the world its Caucasian or white inhabitants. Hitherto our search for the fossil ancestor of the white man has been in vain. Everyone is familiar with the place held by Palestine in our conception of human life at the dawn of history; the excavations made at Mount Carmel by Miss Garrod are destined to give that small country in the East an equally important place in our picture of man's prehistoric world.

What the expedition found was this. Man began to inhabit the caves of Mount Carmel long before the onset of the last glaciation of Europe. One cave from an archæologist's point of view is the richest ever opened; it was filled with fossiliferous earth tramped down by the feet of prehistoric man, until an accumulation more than 80 feet in depth had been formed. From bottom to top the strata were pregnant with man's stone tools, with the fossil bones of animals—many of them of extinct species, and with the bones of the men and women who fashioned and used the tools. It is no exaggeration to say that these deposits record the history of man in Palestine for a period of at least 100,000 years; the period may be longer; the future is not likely to prove that it was shorter. The strata begin while man is still in an early stage of stone culture; they leave off about the time of Abraham. There is no need to tell how each stratum has been made a page of history; the story is told by Miss Dorothy Garrod and Miss Dorothea Bate in a volume just issued by the Oxford University Press [see p. 304 of this issue].

---

* Substance of a lecture given by Sir Arthur Keith at the Royal College of Surgeons on February 14.

Hitherto we have had to build our knowledge of prehistoric man out of fossil scraps. At Mount Carmel complete skeletons were found; one small cave, excavated by Mr. T. D. McCown of the American School, proved to be a veritable cemetery; fossil remains of ten individuals were found in it—three of them complete skeletons—the others were disturbed burials. Altogether we know thirteen of the fossil Carmelites by name or number. We have become familiar with all of them. Four are children, all the adults are less than fifty years of age, save one. Only one had turned fifty at the time of death. The expectation of life was not good among these early inhabitants of Palestine.

We owe so complete a representation of this prehistoric community to certain circumstances: (1) the careful way in which the dead had been buried; (2) to the fact that Mount Carmel is composed of limestone, and limestone tends to the preservation of bones better than any other rock. If the limestone helped to preserve the Carmelite bones, it also made their extraction a matter of extreme difficulty. Mr. McCown, realizing the impossibility of removing the bones piecemeal in the cave, cut out the bone-containing breccia—hard as cement—in blocks weighing a ton or more, and had them conveyed from the slopes of Mount Carmel to the Museum of the Royal College of Surgeons in Lincoln's Inn Fields, London. The rougher work of extraction was done at the Museum but the finer work, including restoration, examination, comparison, drawing and photography of the various bones were done, by permission of the President and Council of the College of Surgeons, at the Buckston Browne Research Farm, Downe, where, within sight of Darwin's old home, Mr. McCown and I restored the old Palestinians to life—or as near to their living state as is now possible. Mr. McCown and I began our task in the autumn of 1933; the final account of what we had done and seen was drawn up for publication at the end of 1937. Thanks to Dr. J. Beattie, conservator of the Museum of the Royal College of Surgeons, our task was made easy.

What kind of people were those early dwellers on Mount Carmel? The Bible records in the book of Genesis that before the flood "there were giants in the land". The fossil people we are now dealing with are almost worthy of such a name. The men were tall; four of them range in height from 5 ft. 8 in. to 5 ft. 11 in. The women, on the other hand, were of short stature, varying from 5 ft. to 5 ft. 4 in. We have been able to study every bone of the feet, hands and limbs of this ancient people; they had straight and strong limbs, walking and running as we do, and yet every bone differs in detail from our bones. Their chests were ample; we infer they were runners and long-winded. We have studied their spinal columns; their vertebræ still retain certain simian details in their conformation. It is so with the bones of their hands and arms; in certain points they are peculiar. We have been able to measure their heads and in some cases to take casts of their skull cavities and thus obtain a crude picture of the conformation of their brains. Although the fossil men of Mount Carmel are separated from us in time by the space of a whole glacial epoch, yet in point of size they had already brains which were equal to ours, although as regards convolutionary pattern, theirs were the simpler. The muscles of their tongues were attached to their lower jaws as ours are; all the parts of the brain which indicate a capacity for speech were present.

In their anatomy they still retained many primitive marks. Their eyebrow ridges, like those of the gorilla, form great bars of bone above the orbits; their jaws are massive; their mouth cavities were very much more capacious than ours. Their necks were thick and exceedingly strong.

Nowhere in the world of to-day could there be found a local group of people showing the wide range of structural variation of our fossil Palestinians. Chins were at every stage of evolution—from a chinless stage comparable to that of the chimpanzee, to chins of moderate development. One of the most distinctive of human features is the nose; in nose-form, the Palestinians were not uniform; in one the size of the bridge and general prominence might well be the prototype of the Roman nose; in another, an opposite condition—almost negroid—prevailed. We found it possible to arrange the individuals of the group in a series; at one end, a woman had her closest affinities to the very primitive Neanderthal type of Europe; at the other end of the series, a man known to us as Skhūl IV might be a crude form of an early European. We seem to be dealing at Mount Carmel with a plastic folk in the throes of evolutionary change.

To fit the fossil Palestinians into their place in our picture of ancient humanity we have to think geographically. We now know that before the last glacial epoch set in, Europe was inhabited solely by peoples of the Neanderthal type; their fossil remains have been found as far west as the Island of Jersey and as far East as the Crimea. As we go eastwards, the type approximates somewhat to that which we have now found in Palestine. In Mount Carmel we have a people whose date is earlier, not later than that of the Neanderthalians of Europe. Our Mount Carmel people have many points of resemblance to the Neanderthalians of Europe, and yet in many they differ. In those points wherein the Palestinians differ from the Neanderthalians, they are Caucasian or modern.

Have we, then, reached the homeland of Europeans in Palestine—the Eden in which Neanderthal man evolved into man of the modern type? That is not the inference Mr. McCown and I are inclined to draw; we believe that, as research is carried further into Western Asia, we shall find the fossil remains of men who have still less of the Neanderthalians in them and more of us moderns than is the case at Mount Carmel.

The first glimpse we have in Europe of the early Caucasians or 'whites' is obtained when the crisis of the last glaciation was passing. They then appear in South Europe as Cromagnons and in central Europe as Predmostians. Hitherto we did not know whence these early representatives of our type had come. The discovery at Mount Carmel suggests that we shall find their homeland in Western Asia. Our tall men of Mount Carmel have many structural points in common with the tall Cromagnon. History, it is said, repeats itself; the Cromagnons blazed the trail from Asia to Europe; the ancient Palestinians may not be the ancestors of the Cromagnons but only distant relatives; at a much later date, Western Asia gave Europe its forms of speech and also, we presume, the primitive speakers of the Aryan tongue.

The most surprising result of the excavation of the caves of Mount Carmel is the light thrown on the mentality of early stone-age mankind. Care of the dead is one of the hall-marks of humanity. The Mount Carmel people had a care for their dead. The youngest child was placed in its grave in a sitting position with limbs flexed under the trunk and arms folded. The tallest of the men had in his embrace the fossil jaw of a boar; we do not suppose it was in a fossil state when placed in his dead arms; we suppose it carried with it a meal of which he had been fond—a pig's tongue. We must also suppose that those who placed the supply of food in the grave beside him believed that death was not the end of life. Even thus early man seems to have softened the blow of death with a hope of immortality.

Another very unexpected discovery was this. When the hip joint of one of the men was cleared of limestone breccia, it was found to be shivered. On closer examination a perforation was found at the centre of the injury, filled in with cave earth. When the earth was removed from the perforation of femur and pelvis and a cast taken of it, we had before us the image of a four-side spear-head. We did not know that such weapons had been invented at so early a date; we believed that the only fighting weapons possessed by men then were stone clubs. A spear to penetrate the whole thickness of the hip joint of a large-framed man and to enter the pelvis as this weapon did must have been finely tempered and driven with exceeding force.

Science News a Century Ago

Solidification of Carbonic Acid

QUOTING from the *Scotsman*, the *Mechanics' Magazine* of February 24, 1838, said: "Mr. Kemp, of Edinburgh, who has been so successful in his experiments upon the liquefaction of the gases, has succeeded in reducing carbonic acid gas to the solid state. This experiment, which had been previously shown in Dr. Hope's class-room, Mr. Kemp exhibited before the Wernerian Society at their last meeting, in the presence of Professors Jameson, Forbes, Graham, Trail, Welsh, Pillans, Dr. Neill, and a number of other scientific gentlemen. The gas requires a pressure of thirty-six atmospheres to reduce it to the liquid form. When the pressure was removed by opening a small stopcock on the condensing apparatus, the cold, produced by the rapid evaporation of the liquid, was so great, that the whole mass was almost instantly reduced to the solid state; and in this condition, although the temperature could not have been less than 180 degrees below zero Fahrenheit, it was handled and tasted by many of the gentlemen present. . . . This is the first time that the solidification of carbonic acid has been accomplished in Great Britain. Many important results may be expected to accrue from it . . . there can be no doubt, that any liquid may be frozen by it, and it will be a powerful agent in producing the condensation of those gases which have hitherto resisted all attempts to reduce them to their liquid form."

Kenneth Kemp, who for some years assisted the professor of chemistry, Thomas Charles Hope (1766–1844), died in 1843 at the early age of thirty-six years.

Reform of the Patent Law

IN the issue of *The Railway Magazine and Annals of Science* of February 1838, is a contribution by Mr. J. Hacket entitled "Suggestions on a New System of Granting Patents for Inventions". After a brief review of the Patent Law at that time and the disabilities inventors suffered from and the loss to society through the discouraging effects of the system which then prevailed, the writer went on to say that nothing short of a new system based upon a new principle was required. "The only measure that I can conceive," he said, "calculated to produce the beneficial effects so much required, is a national institution, in which are a number of suitable apartments, with models, plans and specifications of the most useful machines, manufactures, etc., now in use, patented and unpatented, classed in proper order—over each department in the proposed national establishment, persons suitably qualified should be appointed to arrange in order, protect from injury, and be accountable for every model, plan and specification committed to their charge." Individuals desirous of obtaining a patent were to send notice to the secretary of the institution and, on the receipt of the plans and specifications and a fee of £1, protection was to be obtained for one year. At the expiration of this year, or the patent being put into operation, £5 annually was to be paid.

Wind Measurements at Birmingham

IN a letter published in the *Athenæum* of February 24, 1838, Mr. William Ick, the curator of the Birmingham Philosophical Institution, gave some observations made with a self-recording anemometer and a rain gauge. In a violent gale on December 18, 1837, he said, which continued without intermission for 14 hours, the anemometer registered the highest force of the wind as 16½ pounds on the square foot. This gale was exceeded on December 20 when the highest pressure recorded was 21¼ pounds. Other records were taken on January 2 and February 9, 12 and 15 of 1838. "I shall offer no comments on these facts," he added. "The British Association have voted a sum for the erection of an anemometer at Plymouth, and Mr. Osler has very nearly completed the instrument. If another were erected in the northern part of the island, and several others in distant stations judiciously chosen, in the continents of Europe and America, a comparison of the results might in a few years furnish important information respecting the laws which regulate the force and direction of aerial currents and their influence on temperature, humidity, etc."

The inventor of the anemometer to which Mr. Ick referred was Abraham Follet Osler, who was born in Birmingham on March 22, 1808, and succeeded to the glass-making business of his father, which he carried on until 1876. His self-registering meteorological instruments were installed at Greenwich and elsewhere. He was elected fellow of the Royal Society in 1855 and died at Edgbaston on April 26, 1903.

Societies and Academies

Edinburgh

Royal Society, January 10.

A. B. Wildman and J. Manby: The hairs of the Monotremata, with special reference to their cuticular scale pattern. An improved technique for the examination of cuticular scale margins is described and the sequences of scale form along the fibres are discussed and demonstrated photographically. The sequence on the shield-hair of *Ornithorhynchus* is unique and in this, as in other characteristics, the shield possesses a marked bilateral symmetry. Those tail fibres, which possess no shaft portion, correspond to the shields of the more typical shield-fibres. Support is given to the view that the shields constitute a remnant of a more primitive spinous coat. The authors indicate that changes in scale-form along the fibre are innate and are not caused by attrition.

A. Graham: The structure and function of the alimentary canal of æolid molluscs, with a discussion on their nematocysts. The anatomy, histology and physiology of the alimentary tract of four species of æolid molluscs are described. The digestive gland secretes enzymes, digestion occurs in its ducts and in the stomach. Soluble food is absorbed in these positions and in the gland where particles of food are also ingested. Mucus from buccal and pedal glands secreted over the food appears to prevent the discharge of nematocysts; those stored in the cerata are exploded by mechanical means.

Mary G. Calder: Some undescribed species from the Lower Carboniferous flora of Berwickshire; together with a note on the genus *Stenomyelon* Kidston. Two new species of petrified seeds are described: *Calymmatotheca kidstoni* is a radiospermic, cupulate seed, and *Samaropsis scotica* is a platyspermic, winged seed. *Kalymma tuediana* n.sp., a petiole probably allied to *Calamopitys*, is also described. The species *Stenomyelon tripartitum* Kidston is shown to be synonymous with *S. tuedianum* Kidston. The descriptions are based upon material from the Calciferous Sandstone Series (Cementstone Group) at various localities in Berwickshire; the material is now in the Kidston Collection in the Botany Department of the University of Glasgow.

H. Merton: Studies on reproduction in the albino mouse. (1) The period of gestation and the time of parturition. With the help of a self-recording balance, constructed after the principle of a letter-scale and connected with a kymograph, the hour of parturition can be fairly accurately determined. Two-thirds of the births took place between 4 p.m. and 4 a.m. Of 90 females, 84 were fertilized within 4 days after being placed with a male: they therefore showed a very regular cycle of 4–5 days. The methods are described which can be used to predict the day of birth. The average size of 504 recorded litters during the year was 7·0, the largest (8·3) occurring in August.

Academy of Sciences, December 27 (*C.R.*, 205, 1333–1476)*.

Mme. Léone Walter-Lévy: Neutral magnesium chlorocarbonate.

Alexandre Travers and Hamid Zahabi: The preparation of the hexahydrate of tricalcium aluminate.

Mme. Pauline Ramart-Lucas: The structure and absorption of colouring matters. Isomeric forms of fluoresceine.

Marc Tiffeneau and Bianca Tchoubar: The removal of halogen by silver from the iodhydrines of the α-cyclanediols.

Mme. Yvonne Khouvine and Yoshinobi Tomoda: The total acetylation and methylation of α-d-tagatose.

Henry Gault and Jean Burkhard: A partial synthesis of methyl-cyclopentenolone from wood tar.

Daniel Bodroux and René Thomassin: Syntheses effected with p-cyclohexylbenzyl chloride.

Louis Royer: The orientation of certain alkaline halides by calcite.

Jean Gubler: The structural and palæogeographical unities between Fez and Le Sebou (Northern Morocco).

Georges Choubert: The Lias of the eastern Haut-Atlas and of the Hauts-Plateaux.

Jean Sagatzky: The Tarkwaïen system in Ex-Haute-Volta.

Raymond Jouaust, Robert Bureau and Louis Eblé: The sudden disappearance of radio-electric waves, their relations with magnetic and solar phenomena. From a study of a year's data, it is concluded that chromospheric eruptions cause sudden disappearance of radio-electric waves and, at the same time, small local magnetic disturbances are produced, the latter differing from magnetic storms.

Pierre Dangeard: The presence of pyrenoids in some species of *Vaucheria*.

Jacques Rabaté and Jean Dussy: A new holodiglucoside extracted from sophoraflavonoloside.

Victor Plouvier: The presence of amygdonitril-glucoside in the genus *Cotoneaster* and some other Rosaceæ.

Emile Miège: The baking qualities of *Triticum*, of *Ægilops* and of their hybrids.

Joseph Lefèvre: Some effects observed as the result of the treatment of seeds and cuttings with various substances and especially with heteroauxin.

André Hollande: Amœbæ of the limax type, in their relations with flagellates.

Pierre Drach: The origin of the limestone in the tegumentary skeleton of the crustacean Decapods.

Daniel Auger: The stimulation of an internode of *Nitella* by the current of action of a contiguous inter-node, latent addition.

Marius Piéry, Jean Enselme and Mlle. Simone Pettel: Researches concerning the influence of mineral waters on tissue respiration. The constitution of a system of research by means of Warburg's technique.

Raymond-Hamet: The physiological activity of pure gelsemine.

Mlle. Marie Thérèse Regnier: The action of the sexual hormones on the inversion of sex in *Xiphophorus helleri*.

Albert Raynaud: The histological study of the genital tract of female mice transformed experimentally into free-martins.

Jaques Monod: Maintenance ration and growth ration in bacterial populations.

René Catala: The influence of thermal agents on the nymphosis of the larvæ of *Chrysiridia madagascariensis*.

Mme. Nadine Dobrovolskaia-Zavadskaia: The appearance of a new *culbute* mutation in two different strains of mice.

François Artigas: The absorption by thin screens of the radiation of potassium sulphate and of plant ashes.

---

* *Continued from p.* 300.

Georges Brooks: The determination of the fluorescence spectra of ash isolated from the tissues of *Rana esculenta*.

Lazare Silberstein: The action of chloropicrin on the vitamin B_1 contained in wheat. Chloropicrin is increasingly used for the destruction of insects in cereals: experiments on pigeons show that vitamin B_1 in wheat is unaffected by this chemical.

Mme. Yvonne Jérôme-Lévy: The acetic fermentation in the presence of charcoal. In the presence of charcoal the production of acetic acid is accelerated, and the quantity produced is also higher.

Auguste Cuénod and Roger Nataf: The polymorphism of *Rickettsies* of the trachome.

Arthur Vernes, Robert Bricq and Mlle. Andrée Gager: New considerations on the pallidine of syphilitic sera.

Calcutta

National Institute of Sciences of India, January 9.

Symposium on River Physics in India.

D. N. Wadia: Changes in the courses of Indian rivers during the latest geological epoch.

Sunder Lal Hora: Changes in the drainage of India, as evidenced by the distribution of freshwater fishes.

C. C. Inglis: The use of models for elucidating flow problems based on experience gained in carrying out model experiments at the Hydrodynamic Research Station, Poona.

Gerald Lacey: The flow of water in alluvial channels.

Kanwar Sain: The effects of the construction of weirs and weir-controlled canals on the regimes of the Punjab rivers.

A. N. Khosla: Design of weirs on permeable foundations.

N. K. Bose: River physics laboratories of Europe and America.

S. C. Majumdar: River problems in Bengal.

P. C. Mahalanobis: River floods in Orissa.

Cracow

Polish Academy of Science and Letters, December 6.

Mlle. L. Stankiewicz: The arithmetical operations in the numerical solution of a system of linear equations according to the methods of Banachiewicz.

W. Swietoslawski, L. Keffler and J. Salcewicz: Contribution to the study of the quantity of heat evolved in the internal transformation of a block of lead produced by the action of its own weight. The authors prove the existence of a thermal effect of the order of $0 \cdot 4 \times 10^{-4}$ to $0 \cdot 2 \times 10^{-4}$ calories per gram per hour. When massive blocks of lead are used for measuring the heat given off by radioactive elements, this phenomenon must be taken into account.

J. Moszew: Syntheses of compounds of the type 2′-phenyl-3′, 4′, 2, 3-quinolinoquinoline.

St. Kreutz: The metamorphosis of the amphibolite rocks of the Tatra.

L. Chrobak: Pegmatites and granites containing molybdenite of the western Tatra.

J. Wojciechowski and Mlle. L. Skrobinska: The action of the hydrogen ion concentration on the chemotropism produced by phosphates.

Forthcoming Events

[*Meeting marked with an asterisk is open to the public.*]

Monday, February 21

Imperial College of Science (Chemistry Lecture Theatre), at 5.15.—Prof. W. P. Jorissen: "Reactions in Gaseous and Solid Mixtures".*

Royal Geographical Society, at 8.30.—A. Stephenson and the Rev. Lancelot Fleming: "King George the Sixth Sound".

Wednesday, February 23

Society for the Study of Alchemy and Early Chemistry, at 8.—R. B. Pilcher: "Alchemists' Apparatus in Art".

Royal Society of Arts, at 8.15.—Oscar Borer: "Reclamation of Tidal Lands".

Friday, February 25

Royal Institution, at 9.—Prof. D. M. S. Watson, F.R.S.: "Pterodactyls Past and Present".

Association of Technical Institutions, February 25–26.—Annual General Meeting to be held in the Haberdashers Hall, Gresham Street, London, E.C.2.

February 25, at 11 a.m.—Sir Robert Pickard, F.R.S.: Presidential Address.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Lecturer in Engineering in the East London Technical College, South Africa—The High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (March 4).

University Demonstrator in Engineering—The Secretary of the Appointments Committee, Engineering Laboratory, Cambridge (March 9).

Lecturer in Anatomy in the University of Belfast—The Secretary.

The Scientific Value of Expeditions

THE rescue of the Soviet scientific workers from their drifting ice-floe by the use of two ice-breakers brings to an end one of the most striking polar expeditions of recent years, and one that it is confidently believed will be of considerable scientific value. Any sensational character that this venture may have had was due not to an attempt to accomplish a difficult and hazardous feat as an exhibition of mere physical prowess but to the necessity of adopting a dangerous mode of investigation where no other was available. The inner Arctic regions, which may be taken to embrace all that area of the Arctic Ocean north of the continental shelves of the surrounding continents, has for long defied penetration. Until near the end of the nineteenth century, many attempts had been made to force ships northwards into the pack-ice; but all failed. Other attempts had taken the shape of sledging northwards over the ice from a base as far north as sea access allowed. These attempts were equally fruitless. While such attempts were laudable in an age when the outlines of the distribution of land in high latitudes were unknown, they were nearly always devoid of real scientific inspiration. The nineteenth century tended to measure the worth of exploration by the hardship and danger encountered rather than by additions to knowledge. Thus it substituted for the earlier centuries' motives of commercial gain an aim that was less material but not of higher benefit to man.

It was Nansen who in 1893 realized that to battle with the drifting pack was to play a losing game and that the only sensible course to pursue was to take advantage of its drift—not to move or try to move against the ice but with it. Thus he conceived and carried out his expedition in the *Fram*. On the results of this expedition are based by far the greater part of our knowledge of inner polar regions. Since then, no explorer has emulated Nansen. It is true that several explorers both by sledge and by air have reached or crossed the North Pole, but not one of them has made any considerable additions to our knowledge of high northern latitudes. Hurried journeys, especially at the speed of air travel, have not proved very valuable in scientific investigation. Even broad outlines of the lie of land may give an erroneous impression from the air, as the recent British Graham Land expedition has shown in correcting the aerial surveys of Sir H. Wilkins in the Antarctic. Ground work and sea work remain essential to serious exploration.

The Soviet authorities, in planning this recent expedition, followed Nansen's idea of using the drift of the ice, but by using air transport they were able to begin at the Pole instead of attempting to drift there. The Pole itself had no particular value as a starting-point, but some objective was necessary, and the Pole has a certain lure. The four members of the expedition had few duties to perform outside their scientific work: no energy was dissipated in difficult travelling. All their time was devoted to observation, and as a result we can look forward to a series of meteorological observations taken in high latitudes throughout some nine months. This in itself will be an invaluable contribution to the study of Arctic air currents and all that depends on them. In addition, the observers took regular soundings of the ocean, which will throw light on the position and extent of the submarine ridge which appears to connect Spitsbergen with northern Greenland and probably marks the line of Caledonian folds.

There should also be important observations in the winter phases of plankton and on the physics of the ocean water below the ice, such as the charting of the intermediate warm layer of Atlantic water and its relation to ice formation and wastage The movements of the Soviet floe show a current from Siberia to Greenland, as indicated by the drift of the *Fram*, but as there was no tendency for the floe to be swept towards the north coast of Greenland the drift seems to lack the circulatory motion with which it was often associated. The rate of movement of the floe will determine the rate of the current and the rate of overflow of Arctic water to the Atlantic All these and other observations, not to omit those on magnetism, will amplify the records of the *Fram*, which alone of previous expeditions threw light on these and cognate problems.

Men of science owe a debt of gratitude to these daring Soviet observers and also to the enterprise and sound organization of their rescuers. The Soviet Union has certainly shown extraordinary enterprise and insight in their exploration of Soviet and adjoining polar regions in recent years, and it is much to be hoped that the observations of the drifting station as well as those of the many Soviet observations on land in high latitudes will be readily and soon available to science.

Such a scale of investigation may be beyond the resources or perhaps one should say outside the conception of countries organized on different economic systems. Private enterprise in Great Britain has rarely shown great devotion to exploration without news value and has certainly been diffident about the publication of scientific results. One would like to note a greater tendency to appoint competent observers to the staffs of exploring expeditions. Such expeditions cost much and a great deal of that cost is unwisely spent if the sole results are to be the attainment of records. It is much to be hoped that the scientific side of expeditions, not only from Great Britain but also from other countries, will be strengthened in future along lines suggested by the Soviet Arctic Expedition, which has reached such a happy conclusion.

Lucretius

(1) Lucretius, Poet and Philosopher

By E. E. Sikes. Pp. ix + 187. (Cambridge: At the University Press, 1936.) 7*s*. 6*d*. net.

(2) Lucretius: De Rerum Natura

Translated by R. C. Trevelyan. Pp. xv + 295. (Cambridge. At the University Press, 1937.) 8*s* 6*d* net.

(1) IN view of the small compass of Mr Sikes's book and the steadiness with which the author keeps his object before him throughout, it would be difficult to over-praise his achievement. It is certainly the best and most attractive presentation of the poet which we have in English, and, that being so, its small compass is a strong additional recommendation. Here we have the background and the spirit of Lucretius faithfully described, and in Mr. Trevelyan's book, which Cambridge has also lately published, we have the poems themselves excellently translated. Cambridge has done herself great credit and conferred a signal service on English scholarship and learning by these two works. But in the case of Mr. Sikes's book, 'learning' must be understood in the widest and wisest sense. He gives us not only a mature and well-balanced account of the poem of Lucretius in relation to Greek and Roman writers, but also he estimates—very judiciously on the whole—the origin, truth and permanence of the scientific moral and religious thought which it contains This side of Lucretius will interest us most in these pages; it will probably always be regarded as the most abiding element in his work, however highly we may rate its poetic merits.

Our view, then, in this notice will be rather the converse of that which Macaulay is recorded to have expressed in the marginalia of the Lucretius which he read on his voyage to India. To him the poetry was often "neat and clear" and sometimes even "sublime beyond any passage of the kind in poetry". But the thoughts expressed were "drivelling", "wretched reasoning" or "contemptible nonsense". It would be strange if a writer, capable of the most sublime passages in poetry, were at the same time constantly falling into contemptible nonsense in his thought. The true judgment is much more balanced, though one might go a little farther than Mr. Sikes does in recognizing the "anticipatory" character of the scientific thought embodied in Lucretius. If, as Mr. Sikes admits, "the principles of Greek Atomism satisfied not only Gassendi but Newton", it is surely going too far to say, as he does in the next sentence, that to "look for anticipations of the present day in the Democritean system is misleading". No doubt the modern thinker, with his trained power of observation and his elaborate machinery for measuring and recording results, stands in a quite different position from the old Greek with his unrivalled power of guessing. But the guess has its anticipatory value. The Greeks made men think and examine all the problems of the material world and life.

It is impossible to deny, and easy to underestimate, the intellectual stimulus of such pioneer work. Two great realms of the Epicurean thought, presented by Lucretius, stand out as examples of this, one in which we are now re-interpreting our definitions, another in which we have widely extended our field without disturbing the foundations on which it rests. The first is that conviction of a reign of law throughout the physical world on which the whole school of Democritus, Epicurus and Lucretius laid so much stress. It surely is not true, as Mr. Sikes suggests, that a quite different 'law'—of chance—has now taken the place of this belief in the uniformity of Nature. The law remains, and is in fact more universally observed than ever, as the basis both of our reasoning and our action. But, logically, we have been compelled to re-interpret it differently, by observing that when we reach a certain point in our examination of the infinitesimal, the law of uniformity escapes us and we are driven to take refuge in the idea of the levelling out of differences by a law of uniformity in the whole or the average. It is well known that Max Planck, to whom we owe the quantum theory, is himself one of the stoutest in re-affirming in a new sense the reign of law, and it is almost needless to add that no well-thought-out action, based on science, has been affected by the supposed vagaries of the infinitesimals of our thought.

On the other great department of Epicurean thought there is less to be said by way of re-interpretation, though much more by way of expansion and of deepening its import. This is given in Lucretius's first sketch of anthropology and of the progress of man from the savage to civilization. He is here, as elsewhere, building on the knowledge and thought of the Greeks, who for centuries had been open-minded and curious travellers in all the lands which surrounded them. He gives us at the end of his fifth book a well-knit summary of the result. There is, of course, no trace in it of any idea that man arose from a lower animal form. Lucretius will not hear of any mixed breeding between man and beast and, like a good rationalist, scoffs at the stories of the Centaurs. But on the subject of man's rise as man, he hits on the truth again and again with the insight of a poet enlightened by science. These five hundred lines are one of the marvels of literature and well repay repeated study. The origin of speech, its kinship with gesture, the discovery of fire from lightning, the birth of gods in dreams, the first working of metals, the development of the cultivation of the soil and the later blossoming of ships, laws, walled cities, pictures, statues and all the pleasures of civilization—these all find their place and they are explained much as our fuller knowledge of to-day would explain them. He actually winds up with the first known use of the word 'progress', as denoting the advance of the active mind of man.

It should be added that Mr. Sikes is at his best in appreciating the poetic worth and affiliations of his subject. Lucretius was no mere rhymester of a materialist philosophy but a great and moving poet, himself often moved by, and often using, the imaginative fictions which he would not admit as science. Virgil knew, studied and loved him. It was he in the "Georgics", "felix qui potuit rerum cognoscere causas", and to him may be applied in the fullest sense Longinus's definition of poetry, as amended by Matthew Arnold—"A great subject made great by the greatness of the poet's mind".

(2) It is in this spirit that Mr. R. C. Trevelyan has carried out his labour of more than twenty years in completing a verse translation of the "De Rerum Natura" and publishing it with a modest and most attractive introduction and an appendix by Mr. H. Sykes Davies on Macaulay's 'marginalia' to his copy of Lucretius. This has happily survived and makes most amusing reading. Macaulay evidently unburdened his philosophic soul by these solitary scribblings, much as the Kaiser Wilhelm did on his State-papers, though with less danger to the peace of society. They are very neatly summarized and countered in Mr. Sykes Davies's essay. It adds greatly to the interest of the volume, which will undoubtedly become the standard version of Lucretius in English.

No doubt there are some awkward lines, places where Mr. Sikes and others have done better than Mr. Trevelyan. But these are inevitable and quite subordinate to the general excellence of the whole. It reads as an original and is so readable that it should add many thousands to the number of those who know and appreciate the most remarkable literary relic of ancient Rome, one of the most remarkable of all antiquity.

In language, of course, Virgil is more finished, and for poetry, pathos and charm, much in Greek takes a higher place. But there is nothing in which are combined so much deep thought, argument, moving passages and stately diction—certainly in Latin, possibly even in Greek. As we have seen, it conquered even Macaulay's detestation of its philosophy, and he read it through three times in the course of four years. Nearly all the great questions which have exercised the scientific mind in later times are here raised, often no doubt in a crude and dogmatic shape. But the argument carries one on, and Mr. Trevelyan's verses are clear and generally flowing. He uses the ten-syllabled blank verse as the most familiar of English verse-forms and also the most adaptable to expressing different shades of thought and feeling. Yet it must be said that Mr. Sikes, where he gives us some of his too rare versions of short passages, makes us wish very much for more. Here is Mr. Sikes's version of the most famous line in Lucretius:

"Such crimes could Superstition teach mankind."

That is certainly better, both for sense and sound, than Mr. Trevelyan's

"To such crimes
Religion has had power to persuade mankind."

But we are under a deep debt to them both.

F. S. MARVIN.

Entomo-Museology

Über entomologische Sammlungen (ein Beitrag zur Geschichte der Entomo-Museologie)

Von Walther Horn und Ilse Kahle. (Entomologische Beihefte aus Berlin-Dahlem, Bände 2, 3, 4). Teil 1. Pp. 160 + 16 plates. 15 gold marks. Teil 2. Pp. 161–296 + plates 17–26. 8 gold marks. Teil 3. Pp. 297–536 + plates 27–38. 10 gold marks. (Berlin: R. Friedlander und Sohn, 1935–1937).

THE completion of Dr. Walther Horn's account of entomological collections, entomologists and "entomo-museology" is a matter upon which to congratulate not only the author, but also that numerous race of museum entomologists who have already given it a hearty welcome. The work is, in fact, a revised and greatly expanded edition of the same author's "Über den Verbleib der Entomologischen Sammlungen der Welt" (Suppl. Entom., 1926 and 1929). Those combined papers occupied 182 pages; the present work fills 536 pages. A rough estimate shows that in this new volume some 6,600 entries occur, each giving a collector's name as fully as ascertainable and date of birth, and of death if not still living. This information is followed by a brief, sometimes almost laconic, statement as to the present whereabouts of the collections he formed. As those know who have had the pleasure of personal contact and correspondence with Dr. Horn, he is not only an indefatigable entomologist, but also a keen humorist; perhaps that is why he opens with "Å (Norwegian): see also under Aa"; "Aa" does not occur, except in Aall and in two "Aarons". Incidentally, the first correction in the supplement is "Å is to be deleted"—what a pity to spoil the joke.

The present whereabouts of the many collections to which Linnæus, Fabricius, Esper, Cramer and other early writers so often referred is a matter of keen concern to the serious student of systematic entomology, for without access to these it is frequently impossible to interpret many of these authors' descriptions—unless a guess can be called an interpretation. The information gathered together by Dr. Horn concerning these collections is extremely useful to his 'entomo-museologists'; the utility of some of the entries dealing with more recent collections, is, however, rather more debatable. For example, a statement that the collection of British insects formed by "Smith, H — J — (b —, d —)" was "sold at Stevens' by auction in 1872", to take an imaginary example, does not bear any clear evidence of being a fact of great scientific or even historical interest. But it is easy to criticize; far harder is it to draw the line in a compilation of this kind. In the entomological registers kept in the British Museum now for nearly a hundred years, there must be, at a chance computation, at least 50,000 entries of collections received. Should an abstract of these have been sent to Dr. Horn?

The body of the work is supported by thirty-six plates of reproductions of the handwriting, usually on a label, of a great number of well-known systematists. In museum work, the authenticity of a label is often of great importance; let us hope that these plates will help to solve many a puzzle—one scarcely dares suggest that some of the labels might conceivably have just the opposite effect! It is not until one has passed by all this, however, that the real personality of the author is discovered, for at the end of the work Dr. Horn has added a series of chapters in which he traces the evolution of museum entomology, with special reference, naturally, to Germany and Central Europe. The great names of the past, the old societies, the early publications are woven into a story of the beginnings of entomology such as only Dr. Horn could tell.

The mixture of foresight and fantasy in some of the early writings surely produced its finest blossoms (but no harvest) in Herbst, who in 1781 propounded a plan for the formation of a "German

Entomological Republic". Had the 'laws' of these 'republicans' been enforced, what an amount of labour would have been spared us; for example, descriptions were to be limited to *really* new species, had to be published in a single central journal, and be properly illustrated. One is tempted to quote much from this chapter on the old amateurs; but there is plenty of fun in the next one as well, for here Dr. Horn tells of the birth of the older national museums of Europe—London, St. Petersburg, Vienna, Paris and Berlin—and he is by no means complimentary (and justly so) about the Walkerian epoch of the British Museum. It is only in here that there does seem to be a lapse, for twenty-four pages of criticism of the reform proposals of Dr. Titschack seem rather out of place. Obviously this chapter and the next, which deals historically and discursively with the relation of systematic entomology to experimental zoology, are designed principally for internal consumption. "On lending specimens", is, however, sparkling and very personal; we should not like to incur Dr. Horn's wrath!

These later chapters bubble with facts and ideas, praise, blame and surprises—like Dr. Horn himself, full of the unexpected. Indeed, what better ending could he have chosen than the words he actually uses: "Was that not heroic?" Entomologists, especially those whose work lies in museums, will certainly answer 'yes'; but that is not what he meant.

N. D. RILEY.

A Biochemical Feast

Perspectives in Biochemistry:
Thirty-one Essays presented to Sir Frederick Gowland Hopkins by past and present Members of his Laboratory. Edited by Joseph Needham and David E. Green. Pp. ix + 362 + 6 plates. (Cambridge: At the University Press, 1937.) 15*s*. net.

A SHORT time ago, someone was happily inspired to suggest that a book of essays on modern biochemistry should be presented to Sir Frederick Gowland Hopkins to celebrate his seventy-fifth birthday. As the editors mention in their introduction, "It was felt that no greater tribute could be paid to the doyen of English biochemistry than a concerted creative effort by those who have had the privilege of his inspiration". No higher compliment could be paid to both the recipient and the gift than to suggest that each is worthy of the other.

Perhaps it would not be regarded as too frivolous if this book is likened to a sumptuous biochemical feast. Each dish on the menu has been prepared by a world-renowned chef, and all are gathered together to offer their own creations and masterpieces to a beloved master—the supreme chef, who gave inspiration to so many of them. The organizers of this feast, Joseph Needham and David E. Green, have done their work extremely well, and the arrangement of dishes is excellent.

The first essay, "The Biochemistry of the Individual", by J. B. S. Haldane, certainly has the stimulating action of a cocktail, but in its sustaining and appetite-promoting properties it resembles more closely the *hors-d'œuvre*. After that, there is a long succession of nutritious dishes totalling thirty-one in all, and even the most critical epicure could find fault with very few of the items. Few will wish to partake of every dish, but every biochemist will find food and stimulation in plenty.

Passing now to the more usual form of review, the first point which is of special interest is that most of the authors have shown an eager desire to "indicate the most promising lines of advance" in the fields which they survey, and to speculate a little as to the future. The ordinary scientific publication is usually a very dull article, since it necessarily deals with facts and not fancy. Any tendency towards speculation or dreams, which may or may not be inspired, is ruthlessly dealt with by the editor and his blue pencil. In this book the authors have been given a free hand, and in most cases they have shown their appreciation of this liberty. In consequence the articles are interesting, illustrative and inspiring. No one could read the article by Raistrick, for example, without believing with the author that in the realms of microbiological chemistry "there is an almost inexhaustible field awaiting exploration", while on the other hand Haldane convinces us that it is probably a biochemist who will discover how to influence gene-reproduction in a definite direction.

In a book of this type the personal touch is so often evident, the suggestion that eleven genes may be controlling successive stages in the synthesis of chlorophyll "much as a team of well-controlled Ph.D. candidates would be in a certain type of German Laboratory", and the statement "This simple conclusion gave me the greatest mental satisfaction that I have experienced in my life as a scientific worker. That is why I now offer it to Sir F. G. Hopkins" will perhaps suffice to indicate these features. Authors of scientific papers are usually compelled to write in the stilted third person and it is rather refreshing for once to meet with pronouns of the first person.

Without giving a list of the different chapters, it is almost impossible to indicate the immense field covered by the authors—again a tribute to the widespread interests of Sir Frederick Hopkins. Various aspects of protein chemistry are dealt with by Dorothy Jordan Lloyd, Peters and Luck; muscle by Bernal and Dorothy Moyle Needham; oxidation by Dixon, Krebs, Szent-Györgyi, and Green; vitamins and diet by Friedmann, Sir Edward Mellanby, and Harris; microbiological chemistry by Raistrick; calcium and blood coagulation by John Mellanby; molecular forces and surface films by Adam; biochemistry and mental disease by Quastel. Other articles discuss viruses, insect growth, hæmoglobin, drugs and mankind, and colour variation in flowers.

Sufficient has been said to show that in most cases the authors have consented to indulge in a little harmless but helpful speculation, and possibly because of this, these essays are of a very interesting nature. The articles by Sir Edward Mellanby, Raistrick and Wigglesworth might be quoted as typical examples of essays which will be read time and time again by many biochemists. The average biochemist should find interest and food for thought in at least nine-tenths of the articles. The majority may find one particular chapter rather indigestible, but there is adequate choice, and no one will be expected to assimilate and store the whole of the food provided. To sum up, it might be said that this book is one which every biochemist should buy, and decline to lend to his colleagues, for it is certain that the borrower would never return it. A. WORMALL.

Carl Friedrich Gauss

Carl Friedrich Gauss

Inaugural Lecture on Astronomy and Papers on the Foundations of Mathematics. Translated and edited by G. Waldo Dunnington. Pp. xi + 91. (Baton Rouge, La.: Louisiana State University Press, 1937). 1 dollar.

THIS monograph on Carl Friedrich Gauss, though short, has evidently necessitated a good deal of research, in the "Gauss Archive" at Göttingen, the Gauss Library, and elsewhere. The time of publication coincided with the celebrations arranged to mark the two-hundredth anniversary of the foundation of the University of Göttingen.

The book contains in the first place a sketch of the early life of Gauss from his birth (on April 30, 1777) down to 1803, which is a reproduction (with minor additions, changes and corrections) of an address given in 1933 before the Mathematical Association of America, Kansas Section; and this sketch the editor apparently hopes to expand into a complete biography in a later volume. The rest of the present volume is devoted to translations of two little-known papers by Gauss, with all necessary historical notes and references to the works quoted. The first (six pages only), recently discovered, seems to belong to the early years when Gauss was forced to think of becoming a teacher of mathematics; it is on the foundations of mathematics, and is not abstruse. The second is an inaugural lecture on astronomy, which may be the first of a series of lectures offered by him as his only course in 1808 when he lectured for the first time in Göttingen. It is, as the editor says, interesting in that it furnishes a clear picture of the development of astronomy up to the time of Gauss, and abounds in classical and historical allusions. In this lecture, Gauss quotes with admiration Schiller's charming poem "Archimedes und der Schüler."

The biographical sketch is well worth reading. It appears that two of Gauss's sons settled in the United States, and most of his descendants live there. To two of these, the late Mr. William T. Gauss and his daughter, the editor is indebted for much valuable information and source material. He has many references to Gauss's "Notizenjournal," or diary, the most important guide for dating *seriatim* his principal discoveries. He has also consulted the text-books used by Gauss and now in the Gauss Library, because Gauss was in the habit, all his life, of using the empty pages and the inside of the book-covers as writing-paper for entering not only formulæ and minor calculations but also, often, abstract researches.

A story on p. 36 illustrates Gauss's habit of self-assertion, verging at times on the inhuman. In thanking H. G. Grassmann for a copy of his "Ausdehnungslehre", he wrote that he found in it methods practically the same as those he had himself used for fifty years. Archimedes would not, one feels, in such a case, have written like that. T. L. H.

(1) The Observer's Book of Trees and Shrubs of the British Isles

Compiled by W. J. Stokoe. Pp. 240.

(2) The Observer's Book of British Butterflies

Compiled by W. J. Stokoe. Pp. 191.

(3) The Observer's Book of British Wild Flowers

Compiled by W. J. Stokoe. Pp. 224.

(4) The Observer's Book of British Birds

By S. Vere Benson. Pp. 223.

(The Observer's Pocket Series.) (London and New York: Frederick Warne and Co., Ltd.) 2*s*. 6*d*. net each.

UNLIKE many so-called books for the pocket, these handy volumes are only 5½ in. × 3½ in. and therefore actually will fit a coat or knapsack pocket with ease. From that point of view, and also that of a modest price, the books will prove a boon to those who are in the habit of going into the country on Nature rambles.

(1) 117 species of trees and shrubs are here described, and the text is illustrated by 177 photographs, line diagrams and coloured plates. Unless an inquirer is confronted with a garden escape or is examining some exotic cultivated species, it is scarcely likely that this useful volume will fail him.

(2) Every British butterfly appears to be included in this descriptive list to which reference is made easy by 154 illustrations, 68 of which are in colour. A résumé of the life-cycle of a butterfly and hints on collecting precede the actual detailed descriptions. To refer to this volume periodically, even if one is not fortunate enough to be able to go into the country for practical observation, will give endless pleasure and a good working knowledge of this group of insects.

(3) Though not so exhaustive, this volume will not fail the field naturalist except in very rare circumstances. Two hundred species of flowers are described and the text is illustrated by 120 line diagrams and 100 coloured pictures. The glossary might with advantage have been extended.

(4) 220 species of birds are here described. There are 200 illustrations, 100 of which are in colour. The author, who is honorary secretary of the Bird-Lovers' League, has spent many years in bird-protection work. His enthusiasm seems to have inspired this useful book, which in its turn should easily inspire readers to watch and study but not to destroy.

All four volumes are accurate and reliable—a credit to authors and publishers alike. They will make acceptable presents to Nature lovers and a source of inspiration and delight to hikers and ramblers.

Chlorkautschuk und die übrigen Halogenverbindungen des Kautschuks

Von Dr. Andreas Nielsen. (Chemie und Technik der Gegenwart, herausgegeben von Dr. H. Carlsohn, Band 16.) Pp. viii + 123. (Leipzig: S. Hirzel, 1937.) 6 gold marks.

RUBBER, owing to its unsaturation, is readily open to the formation of addition compounds, and it is somewhat surprising that investigation in this field was so long dormant. Apart from the addition reaction with oxygen—a perennial rubber problem in relation to ageing or perishing—the outstanding group of addition compounds is that formed with the halogens and halogen acids, of which the present book treats. Their relative importance can be judged by the 78 pages devoted to chlorinated rubber, the other seven compounds being dismissed in 26 pages of text.

Chlorinated rubber was first observed in 1835, but it is only in the last fifteen years that its commercial exploitation has expanded under the impulse of over-production of raw rubber and the organized search for "new uses". A large volume of literature has rapidly accumulated, however, partly on patents for the preparation and stabilization of chlor-rubber and partly on the application of the material in varnishes and lacquers, in which the author has had much experience. The present book is an excellent critical analysis of this scattered literature. Tested against the various controversies that the new industry has occasioned—such as, to depolymerize or not before chlorination, stability of chlor-rubber films against heat and water, adhesion of the films, suitable film vehicles—the book is always admirably lucid and balanced in its judgments. The wealth of precise detail in the sections on properties obviously contains much new and valuable work.

Rubber hydrochloride, which bids fair to become an important material for the production of transparent film, is adequately treated so far as existing, somewhat scanty information goes. The other chapters are only slight sketches.

The book is sufficiently indexed, and includes a comprehensive patent list. T. R. D.

Progress and Conquest

By S. Rivers-Smith and W. K. Spencer. (Simple Science in Simple English.) Book 1: The Creation and the World around Us. Pp. vii + 100. 1*s*. Book 2: The Soil and the Plants. Pp. x + 96. 1*s*. (London: Oxford University Press, 1937.)

THESE little books have been written to "realise the ideal whereby no child shall leave school without some knowledge of scientific principles". The language has been related by Dr. Lawrence Faucett to his 1,500-word vocabulary based on frequency principles, words outside that vocabulary being often illustrated by small sketches.

Book 1 is much the better of the two, and is difficult to praise too highly. Chapter iii, "Plans in Nature", introduces the idea of planning and the book is therefore especially significant. It is not true that "all living things come from eggs", but the chapter on "Living Things" is otherwise admirable.

Book 2 is similar in conception though there are some unhappy expressions. "Make or become liquid" is a poor equivalent for "dissolve". There is confusion about the purpose of pasteurization of milk: the tubercle bacillus is not a spore-former. The account of the value of humus is the most commendable feature in the book, which is worth buying for that alone. H. N.

The Physikalisch-Technische Reichsanstalt

Fifty Years of Progress

By a Correspondent

WHEN in the second half of last century the political and economic union of Germany had been effected, it was realized by far-seeing men that the new Reich could only maintain its position in the world, if the exact sciences, which had then reached a stage of development never before thought possible, were given adequate assistance by the State. In particular, there were many urgent physical problems, the solution of which was of the greatest importance for the general weal not only of Germany but also of the whole civilized world. This work could be undertaken only by a large State institute, in view of the considerable financial aid necessary to carry it out. For this reason, the Crown Prince Frederick, Werner v. Siemens, and Count Moltke took the matter up with the Government, and, in spite of much opposition, they obtained in 1886 the sanction of the Reichstag for the foundation of a "Physikalisch-Technischen Reichsanstalt" in Berlin-Charlottenburg. Hermann v. Helmholtz, the most famous physicist of his time, was appointed the first president of the new foundation, and took up his duties as director in 1887.

The institution was at that time unique, and had as its object primarily the development of the technique of accurate physical measurements, and the related establishment and control of the legal units of measurement, as well as the performance of tests submitted to it by industry. The uninitiated often regard measurements of precision as being opposed to the work of the discoverer, whose services they readily appreciate. Nevertheless, the successful activities of the discoverer would often have been frustrated but for the application of precision methods, as strikingly exemplified by Michelson's experiment, the discovery of the rare gases, the investigations on the effect of external fields on spectral lines, and the discovery of heavy hydrogen. Moreover, our belief in the trustworthiness of our conception of the atom is based essentially on the accuracy with which the fundamental constants involved have been determined by a variety of different methods.

The Reichsanstalt can look back with justifiable pride on having had on its staff men of science who, as a result of laborious and often inadequately acknowledged endeavour, have developed many important methods of measurement to an extraordinarily high level, or devised new ones. Of this we have ample testimony, for example, in the "Lehrbuch der praktischen Physik" of F. Kohlrausch, who was the second eminent president of the Reichsanstalt, which has been responsible for editing the book for many years, as well as in the "Elektrische Messtechnik" by that well-known investigator W. Jaeger. The Reichsanstalt has been responsible for the development of much of the standard equipment for measurements of precision which is used to-day throughout the civilized world. We need only mention here the Diesselhorst precision potentiometer, which is free from thermoelectric disturbances, the multiplex-interference spectroscope of Gehrcke and Lau, C. Müller's bolometer, and the Lummer and Brodhun photometer.

The precision methods of measurement were immediately applied to the establishment and control of the legal units in physics, which at the time of the foundation of the Reichsanstalt were subject to great uncertainty and lack of uniformity, a state of affairs equally intolerable to science and industry in all countries. The Reichsanstalt was concerned not only with the establishment of these units with the greatest possible accuracy, but also with their production in a form suitable for practical use. In other words, convenient secondary standards had to be derived from the primary standards. From among the relevant fundamental researches of the Reichsanstalt, which have extended over the whole field of physics, it will suffice if we direct attention here to only a few of them, such as the evaluation of the standard metre in terms of wave-lengths, the determination of the ohm and the related development of precision resistances of manganin, the researches on the standard cell (Weston cell), and those on the silver voltameter. Moreover, as a result of much laborious work, the temperature scale was fixed between the limits of $-259°$ and $+1773°$.

The precision methods devised for these purposes also opened up the way to the accurate determination of a number of fundamental constants that were not previously known with sufficient accuracy, such as the constants of radiation (Warburg, C. Müller), and the mechanical equivalent of heat (Jaeger and v. Steinwehr). We shall give only one example of the progressively increasing accuracy attained in measurements of this kind. Within the relatively short span of thirty years, it was possible to reduce the error in the measurement of the frequency of electro-magnetic waves from one per cent to one part in a hundred millions!

From the start, however, it was evident to German men of science that their work would have only a restricted value if they regarded it only as a service to their own nation and not as a cultural undertaking for the whole civilized world. For this reason they have always endeavoured to maintain a connexion with the advance of scientific work in other lands. Thus the Reichsanstalt has almost always been represented at the numerous international scientific conferences that have been held to fix and control physical and technical units of measurement, and its results have often had a decisive influence on the resolutions passed at these conferences. In particular, co-operation with the important foreign State institutes which have the same aims, for example, the National Physical Laboratory at Teddington, and the U.S. Bureau of Standards in Washington, has been so close that from time to time and also since the Great War representatives of the Reichsanstalt have worked in these other laboratories, and conversely. The importance of the guarantee of trustworthy international physical units is further exemplified by the fact that two presidents of the Reichsanstalt who were scientific men of world-wide repute, v. Helmholtz and Warburg, have taken part personally in international conferences dealing with these questions.

When we consider the enormous quantities of energy and material goods that are bought and sold in the world to-day, and that they are all measured in terms of these units, it is readily appreciated that this problem of units is of supreme importance not only from the scientific but also from the economic point of view. In these matters, insistence must be laid on the very accurate calibration of all measuring equipment. Thus it has been calculated that an error of only one per mille in the polarization apparatus used for the determination of the sugar content of beet would correspond at the present time, in Germany alone, to an annual market value of approximately one million Reichsmarks. Measuring equipment which has been tested at the Reichsanstalt in terms of its standards and by use of its precision methods is to be found all over the globe ; and in the work of scientific investigators and technologists for the welfare of humanity, which cannot be too highly apprized, it has been of inestimable value. The continuously increasing range of the work of the Reichsanstalt is illustrated by the growth in the number of tests which have to be carried out by that institution. The present income from fees for tests undertaken is about twenty times that of the year 1890, and much more than double that for the year 1913.

The progressive rise in the demand for accuracy of measurement which has resulted from the work of the Reichsanstalt has necessarily also brought in its train advances in industrial development. Thus, as soon as it has been certified that the permissible limits of error of a measuring instrument have been reduced, it is incumbent upon industry to strive after increased accuracy in the manufacture of the instrument. This has been especially noticeable in the work of the optical industry.

Since the economic importance of its work in carrying out tests was obvious even to those not directly concerned with physics, the Reichsanstalt has as a rule been granted the requisite funds and equipment by the particular Ministry concerned. On the other hand, the accommodation, equipment and staff necessary for the prosecution of exhaustive and extended investigations in pure science before 1933 were far from adequate. Thus it can readily be appreciated that the development of the Reichsanstalt was determined primarily by its obligations in the matter of testing instruments and the like, whereas the scope of its purely scientific activities lagged behind. It is a great tribute to the idealism and deep-seated scientific enthusiasm of many men who have worked at the Reichsanstalt that, in spite of the obstacles already mentioned, many excellent investigations of the greatest value to pure science have been carried out within its walls.

Included among about 1,500 publications from the Reichsanstalt, with a total of some 18,000 pages, which have appeared since its foundation, there is a large number devoted to problems of pure science. In particular, it should be mentioned here that the important problem of the spectral distribution of intensity of a black body was completely solved experimentally by Lummer and Pringsheim at the Reichsanstalt. The investigations of Hagen and Rubens on the connexion between the electrical conductivity of metals and their optical properties in the infra-red region of the spectrum are outstandingly brilliant in their formulation and execution. They confirmed the existence of the relation between the reflective power and the conductivity of metals, which results from Maxwell's theory. It was at the Reichsanstalt that Goldstein discovered canal rays, and Gehrcke and Reichenheim the anode rays ; here de Haas found experimentally the celebrated relation, fundamental in atomic theory, between mechanical and magnetic moments ; and here Geiger presented atomic physicists with the point-counter, so indispensable in modern research. The list could be extended by further examples, but we have confined ourselves here to those discoveries from which we are already sufficiently far removed in time to be able to estimate their great influence upon physics.

Although it is often difficult to determine immediately the value for our future knowledge of physics of an investigation in pure science, this applies in still greater measure when we consider its significance for applied science or in the field of economics. Here things are not always so simple as in the discovery by E. Gumlich, who has worked in the Reichsanstalt since its foundation, that certain iron-silicon alloys have an extraordinarily small electrical conductivity and excellent magnetic properties. He immediately recognized the great importance of the diminution of eddy current losses, which depend on the conductivity, in sheet, used for the construction of transformers and dynamos. Gumlich's alloy sheet has found world-wide application, and it has been calculated that in Germany alone, by the use of the alloy sheet, industry saves in iron and electrical energy the equivalent of about one hundred million Reichsmarks a year.

Speaking generally, one can say that the statement made by Werner v. Siemens in 1884, in a memorandum urging the foundation of the Reichsanstalt, still holds good : "Almost without exception it is the result of new scientific discoveries, often with no apparent significance, that such new paths are opened up and important branches of industry newly created or revivified. Whether or not the recognition of a new scientific fact has a practical application cannot as a rule be determined until that fact has been systematically and completely investigated, that is, often after an appreciable lapse of time. For this reason, *scientific progress must not be made dependent on material interests.*"

The Reichsanstalt has never lost sight of this point of view, and its researches were never linked up only with considerations of time, for the high scientific value of its work of standardization is also bound up with its research work. In order to appreciate the spirit that has always been cultivated in the Reichsanstalt, it will suffice to mention the names of its presidents, in chronological order : H. v. Helmholtz, F. Kohlrausch, E. Warburg, W. Nernst, F. Paschen, and J. Stark. As already mentioned, the Reichsanstalt had not long been completed (in 1897) before great difficulties had to be faced as a result of the lack of accommodation and funds, and these reacted on its scientific development, in spite of the eminence of those in charge. Thus between 1897 and 1933 the effective area of its buildings increased only by about 35 per cent, mainly due to the construction of a heavy current laboratory (1913) and of a low-temperature laboratory (1927), and the funds available to the Reichsanstalt for its work lagged far behind those which would have corresponded to the enormous development of physics in the same period. But the new National-Socialist Minister Rust, who has been in office since 1933, began immediately to try to improve these conditions, and his Ministry has succeeded in augmenting the available accommodation almost to double its earlier area, partly by renting suitable buildings, and partly by the acquisition of funds for the erection of new buildings, so that the number of laboratories of the Physikalisch-Technischen Reichsanstalt is now seventy-seven. This process of development is still being actively pursued, and Prof. Stark believes that the leaders of the National-Socialist State, recognizing the importance of the Reichsanstalt, will see to it that adequate financial aid is placed at its disposal, for without this the Reichsanstalt cannot fully realize its aims.

Apatite, Nepheline, and Rare-Earth Mining in the Kola Peninsula

PARTICIPANTS in the northern excursion of the seventeenth International Geological Congress in Russia were afforded ample facilities for inspecting recent mining developments in the Kola Peninsula, and especially the unique apatite deposits at Kirovsk. The latter occur within the world's largest known massif of nepheline-rocks, the Khibine Tundra*.

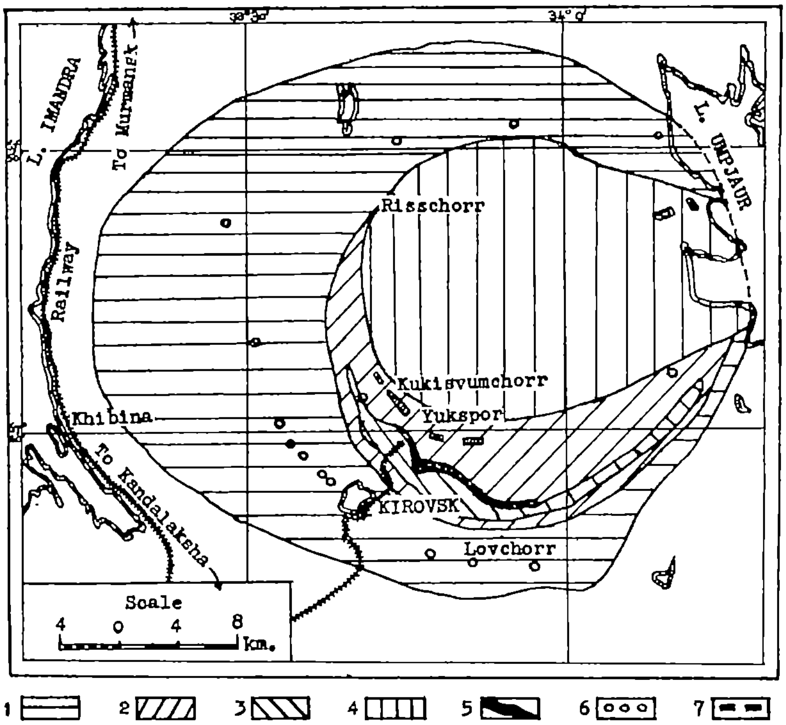
The Khibine massif (Umptek in the Loparian language) has an area of 1385 sq. km. It is of roughly circular outline, with a diameter of about 40 km. The neighbouring Lovozero massif to the east is similarly shaped, with diameter 25 km. and area 485 sq. km. Still farther east there occur great intrusions of alkaline granites, which occupy an area of 3700 sq. km.

The Khibine massif is of annular structure and may be regarded as a lopolith, with steep contacts cutting across Archæan gneisses and the Proterozoic Imandra-Varzuga series. A broad peripheral ring and the central area consist of coarse-grained nepheline-syenites. Along the annular break between these rings a series of younger fine-grained nepheline-syenites, and rocks of the ijolite-urtite range have been injected (see accompanying map). The apatite-nepheline injections which are mined occur as intercalations within the ijolite-urtite series.

---

*The Lapp word *tundra* means the barren uplands above the limits of tree growth, and not the flat, frozen Arctic swamp lands ; hence the Khibine and Lovozero Tundras as names applied to mountain groups.

The less well-known Lovozero Tundra (Lujavrurt) is also built of successive intrusions of the same types of rocks, but it appears to be a horizontally stratified sill-like mass. Both massifs abound in complex zirconotitanosilicate minerals, and minerals containing rare earths as well as niobium and tantalum. As xenoliths of hornfels with imprints of Devonian plants have been found enclosed within the nepheline-syenite of Lovozero, its age is certainly post-Devonian. Radium determinations have shown that the absolute age of the Khibine massif is about 350 million years. Hence Russian geologists assign both intrusions to the period of Variscian diastrophism.



GEOLOGICAL MAP OF THE KHIBINE TUNDRA, KOLA PENINSULA.

1, KHIBINITE (VERY COARSE-GRAINED NEPHELINE-SYENITE); 2, NEPHELINE-SYENITES (FINE-GRAINED TYPES); 3, IJOLITES AND URTITES; 4, FOYAITE (COARSE-GRAINED NEPHELINE-SYENITE); 5, APATITE-NEPHELINE ROCKS; 6, OUTER ZONE OF RINCOLITE AND LOVCHORRITE DEPOSITS; 7, INNER ZONE OF RINCOLITE AND LOVCHORRITE DEPOSITS.

The apatite-nepheline rocks that form the basis of the mining industry are confined to the hanging wall of the ijolite-urtite ring. The ore body is divided into an upper zone consisting of up to 80 per cent apatite and 20 per cent nepheline (average P_2O_5 content, 30·8 per cent), and a lower zone with predominant nepheline (40–70 per cent), and P_2O_5 content ranging from 7 to 22 per cent.

The great new phosphate mine at Kirovsk, developed in eight years, is one of the industrial wonders of the world. This achievement is entirely due to Russian enterprise and energy. Owing to the close collaboration of seven organizations, the U.S.S.R. Academy of Sciences, the Arctic Institute, the Apatite Trust, the Scientific Institute of Fertilizers, the Central Geological and Prospecting Institute, the Rare Metals Trust, and the Leningrad Geological Trust, apatite is now being mined at the rate of 2 million tons per annum, and a reserve of 2,000 million tons has been established. The southern face of Kukisvumchorr Mountain has been blasted back into five broad ledges to a height of 1,500 feet. There are now more than twenty miles of underground galleries seven feet in height, electrically lit, and with electric haulage. A tunnel which admits the ordinary freight train has been driven to the heart of the mountain to facilitate loading. The social and industrial development of the region which, nine years ago, was a desolate arctic waste peopled by a few Lapp families, has kept pace with its scientific and technical investigation. The new town of Kirovsk with 40,000 inhabitants, and villages with the picturesque names of Nepheline and Apatite, have been built, and hundreds of miles of railway has been electrified.

Besides apatite, nepheline is mined for use in the ceramic industry and for its content of potash as fertilizer. The new mineral *lovchorrite*, a massive form of rincolite, chemically a fluorine-bearing titanosilicate of calcium, strontium and sodium, with up to 20 per cent of rare earths, is mined from pegmatites at the rate of several hundred tons a year. Another new mineral, *loparite* (titanoniobate of cerium, calcium and sodium) occurs in deposits of economic importance. Titanite (sphene) is also mined at the new Yukspor Mine, for what reason was not disclosed, but presumably for titanium, and possibly for its content of niobium and tantalum.

Recent Cancer Research

A SUMMARY of recent progress in cancer research is to be found in the fourteenth annual report of the British Empire Cancer Campaign and the thirty-fifth annual report of the Imperial Cancer Research Fund, which were published at the end of 1937. Work from widely distributed centres is described, and the two reports indicate the lines along which the problem of cancer is being attacked.

Dr. P. Stocks, the Medical Statistical Officer at the General Register Office, has continued his investigations on the distribution of cancer of various organs in England and Wales. In the present report of the British Empire Cancer Campaign, he shows how the mortality from cancer of the bladder and of the prostate increases, while cancer of the skin decreases, with diminishing rainfall. This correlation is possibly due to the fact that more water is excreted through the skin and less through the urinary tract under dry atmospheric conditions. The difference is illustrated by a comparison of cancer mortality figures for twelve different sites for Lancashire county boroughs and London. When all sites are considered, the male mortality from cancer is the same in both districts, yet cancer of the skin is almost twice as common in Lancashire, while the mortality figures from cancer of the prostate, of the bladder and of the lung in Lancashire are less than two thirds of those of London. These large differences are probably due to environmental factors such as climate and atmosphere, and support "the hypothesis that certain external factors operating through a man's ordinary environment may be of great importance in determining in what part of the body cancer will appear." The remarkable fact is that though such factors are operating in very different proportions, the same total cancer death rate is found in the different environments.

These findings are of interest from the point of view of factors affecting carcinogenesis which have been discussed by Prof. and Mrs. E. L. Kennaway (*Acta* of the International Union against Cancer, vol. 2, p. 101 ; 1937), who have collected evidence that most cases of cancer are probably due to several intrinsic or extrinsic factors. It is obvious that the differences in cancer mortality found by Dr. Stocks must be largely due to extrinsic factors. Analysis of mortality from cancer of the scrotum in different occupations and of mortality from cancer of the penis in Jews and non-Jews indicates that these forms of cancer are dependent on external factors.

In the report of the Imperial Cancer Research Fund, Prof. M. Greenwood briefly discusses the importance of statistics in assessing the social and economic factors of malignant diseases. He points out that mortality from diabetes is much lower and tuberculosis mortality is much higher among poorer people. Mortality from cancer is also relatively high among lower economic grades, but the differences are not so large as they are with diabetes and tuberculosis.

Much of the experimental work of the Imperial Cancer Research Fund has been concerned with the nature of those tumours which can be transmitted by filterable viruses. Dr. R. J. Ludford has grown fibroblasts and macrophages in tissue culture in the presence of the Rous virus. Under these conditions, fibroblasts were transformed into malignant cells while macrophages were not. This indicates that when infective filtrates of the Rous sarcoma are injected into fowls, the tumour arises among fibroblasts.

Research on the metabolism of tumour tissue has up to the present given interesting results but has been disappointing from a practical point of view. The metabolism of tumours does not appear to be specifically distinct from normal tissues. If some such difference could be found, it might give some clue to the chemotherapy of malignant disease. The carbohydrate metabolism, as shown by the quantitively large changes such as respiration and lactic acid formation, has been examined thoroughly because exact methods for its measurement have been worked out. Recent improvements make it possible to measure the respiration of less than one milligram of tissue. Tumours have a low respiration as compared with their lactic acid formation, but if the respiration were increased *in vivo* it is probable that the rate of growth would be increased rather than inhibited. It therefore appears that other biochemical processes must be investigated in the hope of finding some difference between malignant and normal tissue.

During the past year there has been an increase in the amount of work directed towards the treatment of cancer. The original observation of Dr. T. Reiter that electro-magnetic waves of between 3 and 4 metres wave-length are effective in destroying animal tumours has been confirmed by work carried out at Newcastle-on-Tyne. The action, however, appears to be due to the heating effect of the waves and there is no specific effect of any one wave-length. In order to ensure a cure, mouse tumours must be heated at above 48° C. and rat tumours above 50° for 4 minutes.

The Report of the British Empire Cancer Campaign contains many accounts of clinical results obtained with radium and X-rays. During the year an apparatus has been constructed for the preparation of neutrons to be used to determine their biological effects.

Sir Edward Mellanby has shown that potassium permanganate and iodine destroy the virus of the Rous sarcoma *in vitro*. When iodine is injected into sarcoma-bearing fowls, however, the virus is not destroyed. Workers at Liverpool are still trying to find new lead compounds which will be effective against human cancer and can be safely administered. Researches carried out in the United States have shown that whereas injection of bacterial filtrates into animals with grafted tumours induces hæmorrhage and inhibits growth of these tumours, no such action occurs with spontaneous tumours. Recent experiments performed at the Royal Cancer Hospital show that colchicine, the alkaloid of the autumn crocus, behaves in a similar way to bacterial filtrates, showing the same difference in reaction between grafted and spontaneous tumours. These results indicate that chemo-therapeutical tests are probably best made on spontaneous tumours.

The finding of Dr. A. Haddow that carcinogenic compounds inhibit growth of animals and of tumours has been confirmed in other laboratories. During the past year it has been shown that carcinogenic compounds inhibit the growth of spontaneous tumours, and also that the growth of a tumour which has been induced by a carcinogenic compound may be inhibited by that same compound. If a carcinogenic compound is injected into an animal it disappears, and experiments suggest that the growth-inhibiting action remains when the greater part of the compound has disappeared from the body. Growth-inhibiting power has been found with some substances—for example, acenapthanthracene—which are apparently not carcinogenic.

Derivatives of carcinogenic hydrocarbons have now been prepared in which hydroxyl groups are present and these derivatives have not been found to be carcinogenic. It therefore appears probable that if a carcinogenic compound is abnormally produced in the body from a natural product such as a bile acid or sterol, then the hydroxyl group originally present in the natural product must be removed.

E. B.

Obituary Notices

Prof. L. N. G. Filon, C.B.E., F.R.S.

ON December 29, 1937, the typhoid epidemic at Croydon claimed as a victim Prof. L. N. G. Filon, at the age of sixty-two years, when, in view of his robust frame and vigorous vitality, he might justifiably have been looking forward to many more years of the hard and unselfish work that characterized both his scientific and his public life. His friends had received encouraging news of his struggle against the disease, and the crisis was understood to be over, so that his death came as a shock for which they were ill prepared.

Filon was the son of M. Augustin Filon, the French critic and *littérateur*, who was tutor to the Prince Imperial. Throughout his life he showed a precision and fastidiousness in both the spoken and written word which was, no doubt, due to the atmosphere of his early upbringing, as was also his accomplishment in the French tongue. He started his academic life at University College, London, in 1894, where he had a brilliant career, culminating in the award of an 1851 Exhibition scholarship in 1898. It was at University College that he had his first experience of mathematical research, while acting as demonstrator to Prof. Karl Pearson, for whom Filon always expressed veneration, as witness his speech delivered at the dinner given in honour of Karl Pearson in 1934, when he said, "I had then just taken my degree, and K. P. had taken me upon his staff as Demonstrator, at what then seemed to me the princely salary of £40 a year. Nowadays young people expect at least £250 a year in the same circumstances, but then they do not get the stimulus of a Karl Pearson, which was worth more to me than the difference."

With the 1851 scholarship Filon proceeded to King's College, Cambridge, where he carried out extensive mathematical researches on the theory of elasticity, probably as a result of Karl Pearson's inspiration, since references to Todhunter and Pearson's "History of Elasticity" are frequent. The results are published in several lengthy papers in the *Philosophical Transactions of the Royal Society*. The theory of elasticity remained Filon's chief mathematical interest throughout life. At Cambridge, he also started his experimental work on the behaviour of light in transparent bodies subjected to stress, work which culminated in the standard book "Photo-Elasticity", published in 1931 in collaboration with Prof. E. G. Coker. This work enabled him to make brilliant practical use of that familiarity with the mathematics of stress-distribution which he so eminently possessed. By a foible such as often characterizes great men, Filon prided himself upon being an experimental physicist, although actually his experimental technique was not as highly developed as his mathematical powers.

In 1903 Filon was appointed lecturer in mathematics at University College, London, under the late Prof. M. J. M. Hill, and he became assistant professor of mathematics in 1906, a position in which he continued until 1912, when he succeeded Prof. Karl Pearson in the Goldsmid chair of applied mathematics and mechanics, tenable at University College. It was as a result of his teaching in the Department of Pure Mathematics that Filon produced his standard text-book on projective geometry, now in its fourth edition. He was elected a fellow of the Royal Society in 1910, and in 1935 a member of the Council and a vice-president of the Society, an honour which he much appreciated.

One of Filon's great interests was the University of London Officers' Training Corps, which, as Brevet-Colonel, he commanded from 1926 until 1932. He was already active in this connexion before the Great War, and he went on foreign service during 1914. He commanded the 2nd (Reserve) Battalion London Regiment from June 1915 until September 1916, after which his great technical abilities were more fitly utilized by his appointment to the technical staff of the Admiralty Air Service and of the Air Board.

After the War, Filon began to take an increased interest in the affairs of the University, as a result of which he was elected to the Senate in 1920, on which body he continued to serve until the time of his death. In all that had to do with University administration he showed the characteristic which, perhaps more than any other, distinguished his whole life—thoroughness. Needless to say, his unswerving devotion to what he considered right, and his lack of that praiseworthy pliancy and useful obliquity which adorn some of our leading administrators, occasionally led him to oppose certain notable personalities, but, in spite of this, his services were so outstanding that he was elected vice-chancellor of the University in 1933–35, the period during which the foundation stone of the candid and considerable —may we say elephantine—University building was laid. In spite of his activities in University administration, Filon still found time to produce research of outstanding merit, and to help his students to produce original work.

Throughout his academic life, Filon held that the chief duty of any member of a university staff was to impart learning. He was an excellent teacher and never spared himself, whether the class was large or small, elementary or advanced. He was particularly careful about the organization of exercise classes. One of his enthusiasms was astronomy, and the existence of the University of London Observatory is very largely due to his efforts. He had a deep knowledge of the early history of astronomy, and gave an excellent course on the subject. As a lecturer he had a clear and compelling style, and was well able to adapt himself to a general audience, when he lectured, as he occasionally did, on a general topic.

Filon was a man of wide culture, and one who believed profoundly in the dignity of the academic profession. A congenial companion and a warm-hearted friend, he occasionally indulged in short bursts of irascibility, which, if they arose suddenly, as suddenly subsided. These outbreaks, so well known to his friends, were purely superficial disturbances, for fundamentally Filon was one of the most generous and kindly of men, who would put himself to great trouble even for those who had small claims on him. Nobody could be a pleasanter speaker or a better host. The large numbers which assembled at the memorial service held on January 14 were not brought together by feelings of formal courtesy to a distinguished colleague but came to salute the passing of a great spirit and a great friend.

E. N. DA C. ANDRADE.

Major E. E. Austen, D.S.O.

THE name of E. E. Austen will live as that of a pioneer in the study of Diptera. Educated at Rugby and at the University of Heidelberg, he joined the staff of the British Museum in 1889 as the first curator to have sole and undivided charge of the collections of that order of insects. His first publication (January 1893) was upon a section of the family Syrphidæ (hover-flies), and his second (May 1895) upon the Œstrid genus *Cutiterebra* (American botflies parasitic upon rodents). Quite early in his official career, however, he must have realized that the great amount of undescribed material and the necessity for intensive study made the Diptera as a whole too wide a field for research, and, as at that time the importance of Diptera as vectors of disease was beginning to be understood, he wisely decided to restrict his researches mainly to blood-sucking flies and certain other groups of medical or veterinary importance. It therefore came about that the revision of the Syrphidæ which he had planned was never continued, though he retained his interest in the Œstridæ, publishing several papers on the family so recently as 1933–34.

Austen's interest in blood-sucking flies was doubtless cemented by a visit which he paid to Sierra Leone in 1899 in company with the late Sir Ronald (then Major) Ross, with the object of investigating the mosquitos of Freetown. This was the first expedition sent out by the Liverpool School of Tropical Medicine, and might well have led to his specializing on mosquitos, but he was called for service in the Boer War, and meanwhile the late F. V. Theobald was employed by the Museum to prepare a monograph of the Culicidæ. On his return from South Africa, Austen turned his attention to tsetse flies (*Glossina*) and horse-flies (Tabanidæ). His monograph of the genus *Glossina* (1903) was the first scientific revision of this group, later replaced (1911) by his more concise handbook. His numerous works on other blood-sucking flies include two separate volumes, "Illustrations of African Blood-sucking Flies" (1909) and "Illustrations of British Blood-sucking Flies" (1906), both long out of print, as well as many shorter papers descriptive mainly of African species. More widely known, perhaps, than any of his other publications was the Museum pamphlet which he compiled on "The House-fly as a Danger to Health", which had a very large sale and ran into several editions.

Apart from the expedition to Sierra Leone mentioned above, the only purely collecting trip which Austen made was in 1896, when he and the late F. O. Pickard Cambridge spent three months on the Amazon as naturalists on the cable ship *Faraday*. A greater opportunity for field work came to him during the Great War, when, after a period in France, in command of a company of the Artists' Rifles, he was transferred to the Egyptian Expeditionary Force for special duty in connexion with insect-born diseases. His work on mosquito and house-fly control earned him the D.S.O., and in spite of the arduous nature of this work he still found time and energy to make collections of other Diptera. Arrears of work, and later, official duties when he was appointed first deputy-keeper (1924) and then keeper (1927) of the Department of Entomology gave him little time for studying his Palestine collections. However, his retirement from the Museum staff in 1932 gave him more ample leisure and he turned with zest to the completion of a long-deferred labour of love and eventually (July 1937) produced a handsome volume on the Bombyliidæ of Palestine, which includes descriptions of the numerous species of this family collected by himself.

Austen's descriptive work, though sometimes criticized for a certain lack of conciseness in wording, embodied throughout three qualities upon which he always set a high value: accuracy, consistency and neatness. His neatness was exemplified in the wonderfully clear and firm handwriting, in which he took a just pride, and in the orderly arrangement of the collections under his charge. So precise indeed was this arrangement that visitors not infrequently remarked that the cabinet specimens were like well-trained regiments of soldiers on parade.

Although Austen's published work dealt almost exclusively with the groups of insects which were in his official charge, his interests were much wider. He preferred the Zoological Society to the Entomological Society on account of its wider outlook, and served on the publication committee of the former body. He was at one time vice-president of the Royal Society of Tropical Medicine and Hygiene, a member of the executive committees of the Imperial Institute of Entomology, the British Mosquito Control Institute, and the Society for the Preservation of the Fauna of the Empire. As a colleague he was loyal, purposeful, always anxious to increase the efficiency and prestige of his department, strongly resentful of injustice, and a strict disciplinarian. He was one of the small band to whom the present staff of the British Museum (Natural History) owes, almost entirely, the greatly improved conditions which the staff enjoys. Intensely patriotic, and with a very strong sense of the duty of a citizen, it is not surprising that he looked back with pride upon his service in the "C. I. V." and in the Great War, and that he took a keen and active interest in the local affairs of Northwood, where he had lived since 1913. Those who had the privilege of serving with him will always remember him, a man upright in body and mind, of sterling character, a manly man.

N. D. R. and F. W. E.

Mr. J. L. Starkey

THE murder of Mr. J. L. Starkey, director of the Marston-Wellcome Archæological Expedition to the Near East, in Palestine on the evening of January 10, when he was on his way from his camp at Tell Duweir to Jerusalem to attend the opening ceremony of the new Palestine Archæological Museum on the following day, has deprived field archæology in the Near East of one of its most competent practitioners and exponents.

James Leslie Starkey was born on January 3, 1895, and received his training as a field archæologist under the British School of Archæology in Egypt. When in 1926 Sir Flinders Petrie, owing to the restrictions imposed on archæological excavation in Egypt, transferred his activities to Palestine, Mr. Starkey accompanied him and became his right-hand man. A succession of operations on sites in the neighbourhood of Gaza brought to light important evidence bearing on the periods of the Egyptian occupation, the Hyksos and the early Bronze and Stone Ages of Palestine. More especially significant, perhaps, was the varied evidence which pointed to Palestine having been a centre or gathering point in international relations. This work led Starkey to the excavation of Tell Duweir.

The systematic excavation of Tell Duweir began in 1932. Mr. Starkey, convinced of the importance of this extensive site for Palestinian prehistory by the evidence of surface finds, and more especially by the abundance of potsherds it showed, approached Sir Charles Marston, for whom Prof. John Garstang was then excavating the site of Jericho, and persuaded him to undertake its investigation, at first in co-operation with Mr. H. D. Colt, and afterwards with Sir Henry Wellcome and Sir Robert Mond. The first season's systematic excavation went far to substantiate, if indeed it did not quite fully confirm, his tentative conclusion that Tell Duweir, situated eighteen miles south-west of Jerusalem, rather than Tell el-Hesy, a site some ten miles away excavated many years before by Sir Flinders Petrie, was to be identified with the Biblical Lachish. The site was shown to have been in almost continuous occupation as a position of importance from the early Bronze Age down to the period of Persian occupation, while in the period of the Jewish kingdom when it was probably the centre of the defensive system of Palestine on this front, it had been sacked twice, inferentially by Sennacherib and Nebuchadnezzar—on the second occasion burned. The identification with the Biblical Lachish was borne out later by the discovery here of the famous Lachish letters, the earliest known personal documents in Hebrew, and the earliest example of Hebrew writing. Even more important in the history of written records are the inscribed ewer and copper dagger, on which a primitive form of alphabetic script is held by experts to be closely akin to the Sinaitic script discovered by Sir Flinders Petrie, antedating considerably the earliest known Phœnician alphabetic scripts, which possibly may be derived from it.

This brief notice of Mr. Starkey's work cannot close without reference to one instance of his flair for the importance of a site, of which the full significance was not apparent until last year. This was his foresight in securing for the Marston-Wellcome Expedition the concession to excavate what has since come to be known as the "Bethlehem Bone Beds" (see NATURE, 140, 431; 1937), in which have been found the fossil remains of numerous species previously unrecorded in Palestine, including the first specimen to be found in Palestine of the elephant and also of Hipparion, while fractured pebbles, found in 1937, but still *sub judice*, may turn out to be the first evidence of eolithic man in Palestine.

Mr. Starkey's interests were not confined to the past, and he had taken advantage of the opportunities afforded by the organization of his expedition to secure valuable photographic and other records of the people of Palestine of to-day. By the irony of circumstance, Mr. Starkey met his death at the hands of Arabs, although not only were his relations with his own Arab workmen of the most cordial character, but his scheme of excavation also made provision for ameliorating their condition by instituting cultivation plots on the site as the work proceeded.

WE regret to announce the following deaths:

Mr. W. H. B. Cameron, lecturer in physics in the University of Sheffield, known for his work in spectroscopy, on February 16, aged thirty-six years.

Dr. Ernest Goulding, formerly vice-principal of the Plant and Animal Products Department of the Imperial Institute, on February 15, aged sixty-eight years.

Prof. Gustav Jager, emeritus professor of physics in the Technical High School, Vienna, on January 21, aged seventy-two years.

Prof. Anton Lampa, *Privatdozent* in physics in the University of Vienna, formerly professor in the German University, Prague, on January 26, aged seventy years.

Prof. H. E. Simpson, professor of geography and geology in the University of North Dakota, an authority on the geology of water supply, on January 31, aged sixty-three years.

Prof. H. W. Tyler, emeritus professor of mathematics in the Massachusetts Institute of Technology, secretary of the American Association of University Professors in 1916–33, on February 2, aged seventy-three years.

News and Views

Sir George Simpson, K.C.B., C.B.E., F.R.S.

THE directorship of the Meteorological Office of the Air Ministry of Great Britain is one of the country's most important scientific posts and the recent announcement that Sir George Simpson will retire in September will arouse wide interest and regret. He has had heavy responsibilities. When he assumed office in 1920, his first task was to weld into a coherent whole the very heterogeneous material that the Great War had left behind it, in such a way as to supply the needs of civil aviation, the Navy, the Army and the Air Force, as well as the general public. He shortly had to provide the information demanded by the ill-fated airship programme which came to an end with the *R*101 disaster: this involved a thorough investigation of air motion for use in airship construction and mooring, and an organization for providing route reports for airships in flight such as that which made possible the transatlantic flights of *R*100. Latterly, there has been the organization occasioned by the Air Force expansion and the air mail scheme: accordingly, there is now a section for synoptic work over the North Atlantic and another to give information for the flying boats to South Africa and the East during the first stages of their journeys. Happily, in meteorology, international co-operation is a vital necessity, involving a highly complex arrangement of codes for distributing weather data over the earth; here the British representative has played a very important part. With a fine record of scientific research, both experimental and theoretical, Sir George has shown that, as has often been urged in these pages, executive ability is not confined to those with a literary, political or other training. He is admirable in discussing a purely technical theme; but he is equally impressive in fighting a difficult case through a committee when ingenuity, tact and business capacity have full play; and his success would have been impossible without his obvious courage and sincerity.

Mr. N. K. Johnson

MR. N. K. JOHNSON of the Chemical Defence Research Department has been appointed to succeed Sir George Simpson. Mr. Johnson received his scientific training at the Imperial College of Science and Technology, South Kensington, choosing physics as the main subject for his honours degree. After a period of post-graduate work in astrophysics under Prof. A. Fowler, he went in 1913 to the Hill Observatory, Sidmouth, as assistant to Sir Norman Lockyer and Dr. W. J. S. Lockyer. Relinquishing this post, he served during the Great War in the Royal Air Force, and on the conclusion of hostilities was appointed professional assistant in the Meteorological Office. After a period of service at Shoeburyness, Mr. Johnson was seconded for duty under the War Office at the Experimental Station, Porton. Here he found full scope for his natural inclination towards experimental research work and he tackled with great success the new and difficult meteorological problems associated with chemical warfare. During this period he designed the apparatus described in his well-known paper on "A Study of the Vertical Gradient of Temperature in the Atmosphere near the Ground" (London Met. Office, Geoph. Memoirs, No. 46, 1929). This work yielded much valuable information on the thermal structure of the lower layers of the atmosphere, and has formed the basis of similar work carried out afterwards in other parts of the world. In 1929, Mr. Johnson became Director of Experiments at the Porton Experimental Station, under the War Office, and was promoted later to his present post of Chief Superintendent, Chemical Defence Research Department.

George William Hill (1838-1914)

ON March 3 occurs the centenary of the birth of the American astronomer, George William Hill, who, said Simon Newcomb, "will easily rank as the greatest master of mathematical astronomy during the last quarter of the nineteenth century". His father had emigrated to the United States in 1808 and Hill was born in New York, but his boyhood was passed in the country at West Nyack, N.Y., and there on his little farm he passed away on April 16, 1914, having received some of the highest honours science could bestow. Entering Rutgers College, New Jersey, at the age of seventeen years, he graduated in 1859 and then proceeded to Cambridge, Mass. Early in 1861 he was offered a post under Runkle, the superintendent of the American "Nautical Almanac", and he remained connected with the "Almanac" Office for more than thirty years. In 1877–78, there appeared his new method of dealing with the moon's motion, "his most original contribution to our knowledge of celestial mechanics", and about the same time under Newcomb he took up problems connected with Jupiter and Saturn, and at which he laboured for fifteen years. After the completion of this work he retired from the "Almanac" Office and settled again at West Nyack. "It is difficult," said one writer, "to find such another man as Hill in the whole history of Science. Although holding only a humble post in the 'Nautical Almanac' Office, he lived happily in the liberty it afforded him, and never sought to improve his material position. All he asked for was peace and freedom to prosecute his work". He received the Gold Medal of the Royal Astronomical Society in 1887 and the Copley Medal of the Royal Society in 1909, and France elected him a corresponding member of its Institute. His first paper was published in Runkle's *Mathematical Monthly*, just when he had graduated, and his last in the *Astronomical Journal* in January 1914, three months before he died.

Jacob Da Silva Solis-Cohen (1838-1927)

DR. JACOB DA SILVA SOLIS-COHEN, the founder of laryngology in the United States, was born in New York City on February 28, 1838, of distinguished Spanish and Portuguese ancestry. He received his medical education at Jefferson Medical College and the University of Pennsylvania where he qualified in 1860. After serving for a short time in the United States Army and Navy during the Civil War, he devoted himself to the study of laryngology. His first work on the subject, entitled "Inhalation in the Treatment of Disease", was published in 1867, and was followed in 1872 by his great work "Diseases of the Throat and Nasal Passages", which at once became a standard text-book and ranked with those of Morell Mackenzie (1860) and Francke F. Bosworth (1881) among the classics of laryngology. In 1874, appeared Solis-Cohen's monograph on "Croup in its Relations to Tracheotomy", based on the study of 5,000 recorded cases; in 1875 he published a book on "The Throat and Voice". In 1866, he was the first in the United States to institute regular lectures on laryngology at the Philadelphia School of Anatomy. In 1870 he was appointed lecturer on laryngoscopy and diseases of the throat and chest in the Jefferson Medical College and two years later professor of laryngology. He was one of the founders of the *Archives of Laryngology* and for many years edited the laryngological department of the *American Journal of the Medical Sciences*. He also helped to found the American Laryngological Association, of which he was the second president in 1880–82. As the result of his experience in the Civil War he excelled in the surgery of the upper air passages. In 1892 he was the first in America to perform a successful complete laryngectomy. His death occurred on December 22, 1927.

The Soviet Arctic Enterprise

THE final stages in the rescue of M. Papanin and his three comrades began on February 16, when two planes from the *Murman* and *Taimyr* respectively landed on the drifting floe. It was decided, however, not to remove the men by air since they were in no immediate danger. During the next two days the *Taimyr*, guided by an aeroplane, fought her way through the pack-ice to the vicinity of the camp and on February 18, the four men Papanin, Krenkel, Shirshov and Federov, with all their records and equipment, were taken on board the ice-breakers. The drift had lasted for 258 days and covered about twelve hundred miles. The relief ships *Taimyr* and *Murman*, on emerging from the pack, set out for the port of Murmansk in northern Russia. Congratulations are to be extended to these four men of science and to their rescuers. It is expected that much of scientific importance will accrue from the data obtained at such great risk (see also p. 344 of this issue), and we look forward to the publication of the results when they have been finally worked out.

Pithecanthropus and Peking Man

PROF. F. WEIDENREICH, commenting in another column of this issue of NATURE (see p. 378) on the recent discovery in Java of another skull and a fragment of jaw of *Pithecanthropus*, sets out the grounds for regarding the new evidence, not only as bringing a prolonged controversy to a sudden close, but also as confirming conclusively the close relation between *Pithecanthropus* and Peking man, which he had inferred from his study of the material previously known. From the time of the discovery by Dr.

E. Dubois in the early nineties of the last century of skeletal material in Java, to which he gave the title of *Pithecanthropus erectus*, there has been a division of opinion as to whether these remains were to be classified as human or anthropoid. Of recent years, opinion has tended in an increasing degree to incline to the latter; but recently doubt has been revived. Dr. E. Dubois, after prolonged study not only of the material known to anthropological text-books, the skull-cap, thigh bone and tooth from Trinil, but also of other material from the same provenance in his possession, for the most part not previously published, arrived at the conclusion, mainly on the evidence of the long bones, that we are here concerned with a gigantic gibbon. This conclusion, especially in view of the new material, has been received with respect, but not with general acceptance; and in the light of the new evidence it must be regarded as definitely disproved. *Pithecanthropus* now stands within the line of human descent, if only as a 'prehominid', a class in which Prof. Weidenreich would include him (or her) with *Sinanthropus*, Peking Man. It is interesting to note that Prof. Weidenreich's views as to the close relationship subsisting between *Pithecanthropus* and *Sinanthropus* are fully in accord with the recent conclusion of P. Teilhard de Chardin, who on the palæontological evidence holds that the flora and fauna of China in the early Quaternary period were derived at least in part from the south.

The National Fitness Campaign

AT a reception given by the City Corporation at Guildhall, London, on February 17, in support of the activities of the National Fitness Council, H.M. the King, replying to the Lord Mayor's address of welcome, said that the cause for which they were meeting is one of the first importance, for while we are striving to bring the fruits of education within the reach of all, and to improve the conditions in which everyone may grow and live, we must remember that our bodies are the instruments with which we have to work, and that they, too, need education. In order to become physically fit, all must have the opportunity for regular exercise, and this is what the National Fitness Council and its Area Committees are concerned to promote, and it will be their object to secure facilities for everyone, young and old, to follow his or her own inclination in the method of taking this exercise. The good will and co-operation of all who may be in a position to help being vital to its success, the King warmly commended the movement to leaders of industry and commerce, employers and employed, and to local authorities. In conclusion, addressing youth in particular, His Majesty said, "The future will be in your keeping. The present is your opportunity to fit yourselves for a full, active and therefore happy, life. The decision is left to your free choice. It is for you to make the effort."

British Industries Fair

THE British Industries Fair, 1938, opened on February 21 and will remain open each day until March 4 inclusive, except on Sunday, February 27. As in previous years, the Fair is divided between London and Birmingham. The London Section is held at Olympia and at Earls Court, the latter location taking the place of the White City, which was used last year and for many years before. Again it is to be noticed that only goods manufactured or produced mainly within the British Empire are permitted to be displayed. Among the trades exhibiting at Olympia we may note: chemicals (light and heavy), scientific instruments, photographic and cinematograph apparatus, radio apparatus and plastics, in addition to a large number of other industries usually classified as 'light' industries. At Earls Court, the main exhibits are those of the textile and furnishing trades and an Empire Section. Following the practice of previous years, the Engineering and Hardware Section is at Castle Bromwich, Birmingham. The exhibits here include farm and garden equipment, building materials and products connected with gas manufacture, utilization and distribution, electrical generation and transmission, transport and mining.

IT is interesting to notice that the total space occupied in London is more than 10,000 sq. ft. greater than that taken up for the 1937 Fair, and twenty of the trade sections exhibiting are larger than in 1937. At Birmingham, also, the area taken up by the exhibits is well in excess of the 1937 figure, which was a record. Some eight hundred exhibitors will be represented there, and it is stated that their stands are equivalent to a shop counter of British goods twenty-six miles in length. Holland, for the fourth year in succession, heads the list in the number of trade buyers who are visiting the Fair, Belgium being second, Germany third and France fourth. There is, of course, a large number of Empire buyers from overseas. In the Scientific and Optical Instruments Section at Olympia about twenty-six firms are exhibiting. This section of the Fair has grown considerably. Not many years ago, only a few firms exhibited and their stands were scattered indiscriminately. To-day this section occupies a prominent position in the main gangway, in which more than 5,500 sq. ft. are occupied in a combined display of all kinds of scientific apparatus. The instruments displayed include those used for research, medical, educational, industrial, and navigational (both marine and aerial) purposes. A review of the principal exhibits having scientific interest will be given in a future issue of NATURE.

The Proposed Thames Barrage

AT the meeting of the Metropolitan Water Board held on February 18 the report of the Works and Stores Committee on the proposal to construct a barrage across the River Thames at Woolwich came up for consideration. After relating the circumstances which have led to the institution of a public inquiry into the scheme by the Port of London Authority, the report pointed out that the Board's interests are materially involved in respect of the large filtration works adjoining the Thames at Barn Elms and Barnes where there are, in addition to primary filters at Barn Elms, 5 and 19½ acres respectively of slow sand filters from which a total of 27–31 million gallons a day of filtered water is obtained. The top water level of these filter beds varies from 11 ft. to 16 ft. above Ordnance datum, while the bottoms of the filters lie between 4 ft. and 9 ft. below the same datum. Were the water in the Thames to be permanently impounded, as contemplated in the scheme, the level of the ground water would be raised to a height substantially above the floor level of the filter beds, and these would accordingly stand in a body of polluted water, a condition for which they were not designed, and would be beset with risks of contamination to the filtered water. Another danger would be the increased external pressure against the structures during the periods of evacuation for cleaning. The report went on to show that the reception into the river of sewage and storm water laden with sedimentary matter of a putrefactive and infective character within the limits of the impounded area, would induce in the summer season insanitary conditions, resulting in demands for the release of increasing volumes of water over Teddington Weir in order to abate the nuisance, and that this would jeopardize the integrity of the Metropolitan supply at a time of high water consumption. The report concluded with a strong recommendation to offer strenuous opposition to the scheme.

Galloway Hydro-electric Power Development

AT the Institution of Civil Engineers on February 22, a series of papers was read dealing with the inception and execution of the undertaking belonging to the Galloway Water Power Co., situated in the south-west of Scotland and occupying the southern portion of the mountainous region which lies between the estuaries of the Clyde and the Solway. The first paper by W. Hudson and J. K. Hunter gave an account of the initiatory stages and constructional details of the work. The area which has been developed includes the entire catchment (345 square miles) of the Galloway Dee, with, in addition, a further 50 square miles to the north-west, forming the catchment area of Loch Doon. With a slight exception, all the works lie on the greywacke formation, having a soft and shaly consistency. The climate is mild and the rainfall comparatively heavy, varying from 40 inches per annum on the coast to the south to more than 90 inches on the high ground between Loch Trool and Loch Doon. The more important works in their natural sequence consist of the Loch Doon storage reservoir, which provides main seasonal storage for the upper three power stations on the Dee, having an available capacity of 2,930 million cu. ft. and a total draw-down of 40 ft. The original level of the loch has been raised by 27 ft. Then come the Doon-Deugh tunnels by which water is drawn from the reservoir and discharged, as required, into the Dee. A series of three power stations have been installed at Kendoon, Carsfad and Earlstoun, normally operated together. A fourth station at Glenlee with a reservoir at Clatteringshaws Loch, and a fifth station at Tongland complete the chain of development. The paper by W. Hawthorne and F. H. Williams described the mechanical and electrical plant, consisting of eleven main generating sets with outputs of 6,000–12,000 kilowatts, the total rated capacity being 102,000 kilowatts and the voltage 11,000. The third paper, by H. W. Mountain, co-related the scheme with reference to the Grid, by which the bulk of the output is exported, half to central Scotland and half to north-west England. The total expenditure on the Galloway Development amounted approximately to £3,000,000 and the work was completed in the autumn of 1936.

Planning in a Democratic Government

IN an article, "The Place of 'Planning' in a Democratic Government", in the *Nineteenth Century* of December, Sir Daniel Hall discusses some of the reasons for the apparent inefficiency of democratic Government as compared with the efficiency of totalitarian States, and particularly with reference to the position of the technical expert in democratic administration. The problem of parliamentary Government, he suggests, is that of introducing planning into its administrative machinery to an extent which will permit a degree of foresight in the conduct of public affairs that will take long views, anticipate the effect of material progress on the social organism and concern itself with matters affecting the national welfare which have but little popular appeal. Sir Daniel Hall points out that the conception of planning has already entered our system to some extent, but our schemes are usually piecemeal and without provision for the consideration of their place in the national economy as a whole, while technical opinion is liable to be over-ruled and decisions determined less on intrinsic merits and informed criticism of proposals than by the volume of opposition aroused.

SIR DANIEL HALL considers that it is on this question of expert advice and authority that the British administrative system is weakest, although in recent years successive Governments have come to recognize the need for technical advice and established such bodies as the Development Commission, the Department of Scientific and Industrial Research and the Medical Research Council. These bodies and particularly the Economic Advisory Council provide the nucleus of an organization which could exercise the function of planning within the ordinary machinery of Government, and Sir Daniel Hall suggests that the Economic Advisory Council should be replaced by a Planning Council with a strengthened personnel and a technical staff, linked with the Research Councils. The Planning Council would remain an advisory body with the immediate function of advising the Cabinet or the departments on any question submitted to it. Its most important function, however, would be its initiative in planning, and its constitution would afford men eminent in the industrial, commercial, financial and scientific world opportunity of putting forward their ideas, obtaining criticism from their fellows in all walks of life and collecting the relevant data before formulating a plan of action. Its deliberations would be almost wholly concerned with matters upon which the modern developments of science have a bearing, but it would possess no power of action nor publicity. None the less, Sir Daniel Hall suggests that in this way those responsible for government would be supplied with the services of the expert in a way comparable with that in which Fascist and Communist Governments are served.

Scientific Study of Foreign Policy

THE report on the work of the Intellectual Co-operation Organization submitted by the Sixth Committee to the Assembly of the League of Nations refers to the way in which the scientific study of problems of foreign policy is obtaining recognition as a new branch of learning. The International Studies Conference has devoted two years to the preparation of the study of peaceful change, and as a result of research in many countries a series of works on demographic problems, the distribution of raw materials and colonial questions which would offer reliable contributions to the solution of such problems is about to be published by the Institute of Intellectual Co-operation. The next two years are to be devoted to the study of economic policies in relation to world peace. An international conference on higher education held at the Institute dealt with such problems as the organization of various university faculties, scientific research and higher technical education, overcrowding in the universities and international collaboration. A Permanent Committee on Higher Education was appointed by the Conference to keep in touch with these questions. The report directs special attention to the programme of activities drawn up by the Intellectual Co-operation Organization and the Executive Committee of the International Council of Scientific Unions, which is directly connected with the advancement of all branches of science. The Organisation has also been requested to consider what steps might be taken to enable writers to continue to carry out their work with full freedom of thought and expression and a guarantee of material security. Reference is made to an international inquiry into the reorganization of secondary education, the key to the problem of overcrowding in the universities and liberal professions, and finally the report outlines a draft Act to set up and maintain National Committees on Intellectual Co-operation and to grant financial contributions to the International Institute of Intellectual Co-operation.

Automatic Control for Aircraft

ANOTHER step towards the elimination of the physical and nervous strain upon the pilot in a long flight, caused by his having to maintain continuous manual control over the machine, has just been accomplished by the linking up of several separate devices into one synchronized piece of apparatus for use in such cases. A De Havilland "Dragon" passenger aircraft has been acquired by Messrs. Air Travel and Survey, of Sydney, for photographic survey work. The technique of this demands that the machine must fly on a dead straight line and a level keel for periods, and an automatic pilot that can control this while the crew attend to other photographic duties has been in existence for some time. This apparatus in its latest form, known as a 'deviator', keeps the machine on a given course, but the direction of this must be controlled by the pilot. The new apparatus adds to this a Marconi Wireless 'homing' device which sets the aircraft's course in the direction of the transmitting station, when tuned in to that wave-length. The station would normally be an aerodrome with a special call sign, but ordinary broadcasting stations may be used, provided that the pilot can identify them. He thus has nothing to do except to watch and adjust the wireless receiving apparatus as necessary. This machine was successfully demonstrated on February 17 at Croydon. It brings within sight the day when the pilot of a big aircraft will merely have to exercise a general watch over the instruments in his cabin, more comparable with the manner in which the captain of a ship controls his craft.

Radio Research in India

REFERENCE has been made from time to time in the columns of NATURE to the desirability of encouraging the carrying out in India of fundamental radio research of the type sponsored by the Radio Research Board in Great Britain. This matter was referred to in the presidential address prepared by the late Lord Rutherford for the recent Silver Jubilee meeting of the Indian Science Congress. It was pointed out that the investigations conducted in Great Britain on the propagation of radio waves over great distances have considerably increased our knowledge of the upper atmosphere. The details of the electrified regions of the atmosphere vary considerably with the hour of the day and with the season of the year as well as with geographical location. The results are of great practical importance in the selection of the most suitable wave-lengths for radio communication, and, in addition, it does not seem impossible that such studies may prove of value in long-range weather forecasting. There appears, therefore, to be scope for research on this matter in a wide field and in various parts of the world, and Lord Rutherford expressed the hope that it will be vigorously pursued in India. Reference was made to the very promising beginning that has already been effected by Profs. S. K. Mitra and M. N. Saha and their students in attacking fundamental radio problems. As an instance of the important work which is in progress in other parts of the Empire, mention was made of the admirable progress made in this field by the Australian Radio Research Board, which was established nearly ten years ago.

Research in Foot-and-Mouth Disease

THE Minister of Agriculture and Fisheries has decided to enlarge the Foot-and-Mouth Disease Research Committee. The scope of the problem under investigation has become wider than was envisaged when the work was begun fourteen years ago. There is increasing evidence of the necessity for pursuing the intensive study of this particular member of a group of diseases affecting human beings, animals, and plants in close relationship with investigations into virus diseases generally, and of enlisting the experience of workers in other fields of virus research in the elucidation of the problems connected with foot-and-mouth disease. It has been decided in the circumstances that it would be an advantage if the Agricultural Research Council and the Medical Research Council were more actively and directly associated with the work of the committee than at present, and the following have therefore been appointed additional members: Prof. S. P. Bedson, professor of bacteriology in the London Hospital Medical College; Prof. T. Dalling, professor of animal pathology in the University and director of the Animal Diseases Research Institute, Cambridge; Major G. W. Dunkin, director of the Agricultural Research Council Field Station; Mr. G. M. Findlay of the Wellcome Bureau of Scientific Research; Prof. H. B. Maitland, professor of bacteriology in the University of Manchester; Prof. F. C. Minett, director of the Research Institute in Animal Pathology, Royal Veterinary College, and Mr. J. Henderson Smith, head of the Department of Mycology, Rothamsted Experimental Station.

Fire at the Lister Institute, Elstree

A FIRE occurred in the chemical laboratories of the Serum Department of the Lister Institute, Elstree, on February 21; the cause was the explosion of an acetone-distilling apparatus. The chemical laboratories, dark room, and balance room were completely destroyed, but the adjoining bacteriological laboratories and cold-storage rooms, together with valuable stocks of antitoxins, therapeutic sera, vaccine lymph, and a considerable amount of experimental material were saved through the prompt and efficient work of the staff at Elstree and the local fire brigades. The chemical laboratories were a recent addition to a block of buildings erected by the Institute in 1903 when the Serum Department was under the direction of the late Prof. George Dean. These were afterwards occupied by Mr. Sydney Rowland whilst he was carrying out research for the Indian Plague Commission.

Control of Vehicles in Streets by Traffic Signals

A PAPER on street traffic signals by F. G. Tyack was read to the Institution of Electrical Engineers on November 4. The descriptions and illustrations given show that modern street traffic signal equipment bears a remarkable similarity to telephone exchange equipment. It is proved that where complex switching is required, electrical switching telephone apparatus with its ready adaptability forms an ideal solution. Apart from the contribution of the telephone industry, which applies principally to the controllers, other branches of the electrical industry, such as supply lamps, cables and rotating machines, are represented in the necessary equipment. The earliest road signals were manually operated and the mechanically controlled 'fixed time' signal came next. This type consists of a mechanism arranged to measure off arbitrarily determined 'go' and 'stop' periods. Fixed time signals was a cheap method of solving the problem of accident prevention. They are found unsuitable when the traffic is variable, as they cause unnecessary delays and bring automatic signals into disrepute. The logical solution of the problem is that the signals must be operated by the vehicles themselves. The top of a rubber mat projects slightly above the road level. As the channels in the mat are depressed by the wheels of a vehicle, miniature bellows in the contact box become inflated and an electrical contact is made. Impulses indicating the speeds of the vehicles are thus transmitted to the controller. A further step in advance is to have a master controller which, in conjunction with a traffic 'integrator', adjusts the speed of the signal indications to suit the particular traffic density at the time.

Leyden University Botanical Gardens

THE 350th anniversary of the foundation of the Leyden University Botanical Garden has recently been celebrated. It is the oldest botanical garden in Europe after that of the Vatican (1447), Leipzig (1542), Pisa (1543), Padua (1545), Florence (1546) and Bologna (1567). Only the Gardens of Leyden and Padua have remained in the same place since their foundation. The first catalogue of the Leyden Garden drawn up by Clusen in 1594 contained more than a thousand species of plants, and in the time of Boerhaave this number had risen to 5,800. Numerous Japanese plants were added to the Garden by von Siebold in the nineteenth century.

Medical Research in Canada

THE conference on the organization of medical research which was held in Ottawa on February 18, and was attended by the Governor-General, has resulted in the formation of a National Medical Research Committee for Canada with five members, who have power to nominate ten others. The chairman is Sir Frederick Banting, professor of medical research in the University of Toronto, and the other members are Major-General A. G. L. Macnaughton, president of the National Research Council; Dr. R. E. Wodehouse, the Deputy Minister of Health and Pensions; Dr. T. H. Leggett, president of the Canadian Medical Association; and Dr. G. S. Young, president of the Royal College of Physicians and Surgeons of Canada.

The Night Sky in March

THE date of the Spring Equinox is March $21^d\ 7^h$ U.T. The moon is new on March 2 at $5{\cdot}7^h$, and on March 31 at $18{\cdot}9^h$; full moon occurs on March 16 at $5{\cdot}3^h$. Lunar conjunctions with the planets occur as follows: on March $4^d\ 6^h$ with Saturn; on March $5^d\ 15^h$ with Mars; on March $28^d\ 7^h$ with Jupiter. On March $18^d\ 0^h$ Venus and Saturn are in conjunction; on March $20^d\ 5^h$ Mercury and Venus, and on March

$28^d\ 22^h$ Mars and Uranus. The occasion of the fairly close proximity of Uranus to Mars may be used for locating the latter with binoculars, the magnitude of Uranus being about 6·0 and that of Mars about 1·5. Mars sets at $21{\cdot}7^h$. Mercury is at greatest eastern elongation on April 2, so that towards the end of March there is a chance of seeing this elusive planet in the evening twilight. Venus is likewise an evening star, but sets less than one hour after the sun until the latter part of March. Saturn is passing out of view as an evening star and is in conjunction with the sun on March 29, but Jupiter now rises in the early dawn as a bright star of magnitude − 1·6. In the late evening in the middle of March, the bright stars of Orion and Sirius and Procyon are being lost to view towards the west, but there are compensations. For a small telescope, the double star, Castor, is an excellent subject for observation. γ Virginis is another well-known binary the period of which is about 180 years. 12 Lyncis (R.A. $6^h\ 39^m$, Dec. 59° 31′ N). and 11 Monocerotis (R.A. $6^h\ 25^m$, Dec. 7° 0′ S.) are both triple stars. There is a stellar cluster, Messier 35, north-preceding η Geminorum, and the cluster Messier 44, better known as Præsepe, south-preceding γ Cancri. Away from the obscuration effects of the Milky Way, remote space can be explored with powerful photographic telescopes. In Leo, there is a remarkable group of extra-galactic nebulæ (*NGC* 3185, 3187, 3190 and 3193) exhibiting a variety of types and at a distance of about 7½ million light years from the earth. Another group in Boötes and one in Ursa Major (overhead about midnight in the middle of March) give Doppler displacements in the spectra of the component nebulæ equivalent to recessional velocities of about one-seventh the velocity of light itself; the inferred distances are of the order 230 to 240 millions of light years.

Announcements

Dr. Antoine Lacassagne has been nominated director of the Paris Radium Institute in succession to Prof. Claude Regaud.

The International Conference of Naval Architects and Marine Engineers will be held in London on June 16–18. Further information can be obtained from Mr. P. W. Thomas, 39 Elmbank Crescent, Glasgow.

Dr. G. W. Tyrrell gave an address before the Royal Society of Edinburgh on February 7, on the seventeenth International Geological Congress held in Moscow in 1937, in which he described the Congress meetings, at which 72 per cent of the 422 papers presented were by Russian authors and dealt with Russian geological topics. Excursions to the Kola Peninsula and Karelia, and to the Urals and western Siberia, were then described, and the almost illimitable mineral wealth of the U.S.S.R. illustrated (see also p. 354 of this issue).

The Bureau of the United States Census has recently issued a survey of deaths from motor-vehicle accidents in 1937 showing that in 128 major cities of the United States there were 9,964 deaths in 1937 as compared to the 9,308 in 1936—an increase of 7 per cent. Most of the cases occurred in the first six months of the year. 66 cities showed an increase, 57 a decrease and 5 had the same number of deaths as in the previous year.

A Scientific Book Club has been formed to enable the inquiring layman to keep abreast of the latest developments in modern science and to build up a first-class library of scientific books at a considerably reduced price. Each month the Scientific Book Club brings to its members a recently published book which is of outstanding scientific importance. The books are not confined to any particular publisher but are chosen strictly on merit from the various publishing houses, thus ensuring the widest possible field for selection. Further information can be obtained from the Secretary, Scientific Book Club, 121 Charing Cross Road, London, W.C.2.

In view of the great interest aroused by the National Institute of Industrial Psychology's report No. 7 ("Improving the Blackboard", by W. Douglas Seymour), the Institute has decided to hold a small exhibition of suitable primrose-coloured boards of different materials and of the chalks for use with them. The exhibition, which is non-commercial in character, will be held at the Institute, Aldwych House, London, W.C.2, during the fortnight beginning February 28. From Monday until Friday in both weeks it will open at 9.30 a.m. and close at 5.30 p.m. except on March 1 and 8, when it will close at 1 p.m.

The British Non-Ferrous Metals Research Association, in co-operation with the Swedenborg Society, will shortly publish a translation of Swedenborg's famous treatise on copper, "De Cupro", originally published in Latin in 1734. No translation has hitherto appeared. This book gives an account of the smelting and refining of copper as practised in many countries at the time; the production of brass; the nature of copper ores and their assaying; and various other matters pertaining to the properties of copper, its alloys, and its history. Communications on the subject should be addressed to the British Non-Ferrous Metals Research Association, Regnart Buildings, Euston Street, London, N.W.1.

The Trustees of the Lady Tata Memorial Fund invite applications for grants and scholarships, in the academic year beginning on October 1, for research in diseases of the blood, with special reference to leukæmia. Grants of variable amount are made for research expenses or to provide scientific assistants to senior workers. Scholarships are awarded as personal remuneration; their value will not ordinarily exceed £400 per annum for whole-time research, with proportionate adjustment for work on a part-time basis where this is approved. The grants and scholarships are open to workers of any nationality. Applications must be submitted before March 31, 1938, and the awards will be made in June. Further particulars and forms of application may be obtained from the Secretary of the Scientific Advisory Committee, 138 Bedford Court Mansions, London, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 375.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Structure of Metals

In a recent note with the above title[1], Dr. A. Müller has described interesting effects which are observed when metals are investigated at high dispersion with X-rays. When X-rays fall upon a stationary specimen of metal, and are reflected back through nearly 180°, the reflection from the individual crystal grains appears as a number of distinct spots. If the specimen is rotated during the exposure, smooth Debye-Scherrer lines appear, the centres of which are accurately measurable (in precision measurements of spacing the specimen is always rotated for this reason). In referring to the distinct spots he obtains with the stationary specimen, Dr. Müller says, "the surprising fact is that they are scattered over a comparatively wide range . . . thus indicating lattice variations in the individual crystals of the order of 1/1000–1/2000."

If this deduction were right, it would be rather disturbing, since the accurate estimation of lattice spacing, which is so important a feature in X-ray technique, would appear to be meaningless, or at any rate would only represent a statistical average. We think it possible, however, that Dr. Müller's results may be explained by the optical considerations which are described below; this possibility in any event should be fully explored before adopting the rather revolutionary conception of wide variations in spacing as a general feature of the crystalline grains.

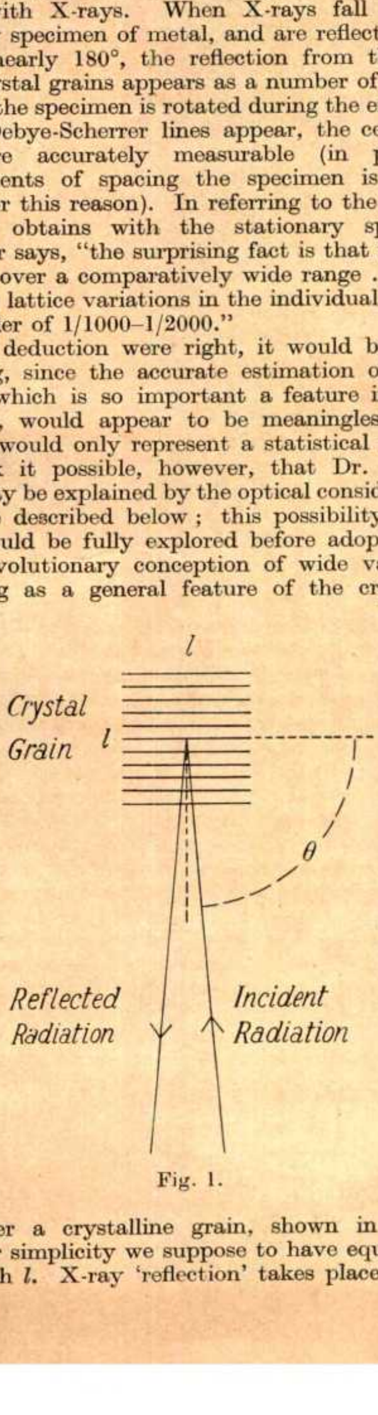

Fig. 1.

Consider a crystalline grain, shown in Fig. 1, which for simplicity we suppose to have equal width and depth l. X-ray 'reflection' takes place over an angular range on either side of the mean glancing angle θ_0, which is nearly 90°; the smaller the crystal the wider is this range. The intensity of the diffracted radiation at an angle $\theta_0 + d\theta$ is governed by the product of two factors which represent:

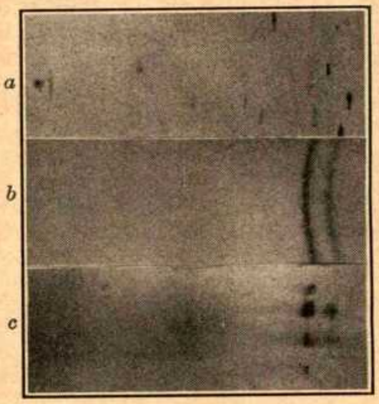

Fig. 2.

(*a*) *The interference between beams coming from successive crystalline planes.* The total range $\delta\theta$ between zero values of the factor on either side is given by

$$\delta\theta = 2\lambda/l \cos\theta.$$

(*b*) *The diffraction of radiation after specular reflection at each crystal plane.* Its angular spread is similar to that of waves passing through a slit of width $l \sin\theta$, and the range is given by

$$\Delta\theta = 2\lambda/l \sin\theta.$$

A. H. Compton pointed out in 1922[2], that when $\theta_0 < \pi/4$, $\delta\theta$ is the smaller, and defines the sharpness of a diffracted beam, whereas when $\theta_0 > \pi/4$, it is $\Delta\theta$ which is the smaller. In Dr. Müller's experiment, where $\theta_0 = 85\frac{1}{2}°$, $\Delta\theta$ is about ten times as narrow as $\delta\theta$.

To see what this means, we may imagine the crystal grain to be rotated through a small arc (of the order of a degree). In any one position it gives a narrow spot of width $\Delta\theta$. This spot appears as the crystal rotates over the whole range $\delta\theta$, being strongest at the centre of the range. Alternatively, if the specimen is stationary, individual grains give sharp spots, which are staggered throughout the range $\delta\theta$ as determined by (*a*) above, although the grains have identical lattice spacings.

It is easy to test this explanation by giving the specimen a 'micro-rotation' over a small angle. The spot due to each crystalline grain is then drawn out into a smear having an intense centre, and fading away on either side. If the grains have different lattice spacings as Müller suggests, the maxima of these smears should be staggered. If, on the other hand, they have the same spacing, the maxima should all fall into place below each other.

Fig. 2 shows the result of such a micro-rotation. The same specimen (a copper wire) was used for all three photographs, the lines being the K_a doublet of cobalt radiation, reflected in the 400 order ($\theta \sim 82°$ for α_1, 83° for α_2). Fig. 2*a* shows the spots produced by individual grains when the specimen is stationary, and it is indeed surprising how much the spots are staggered. Fig. 2*b* shows the ordinary Debye-Scherrer lines when the specimen is completely rotated so that numerous grains pass through the reflecting positions. Fig. 2*c* shows the effect of extending spots similar to those of Fig. 2*a* into smears by a rotation of 3°. It will be seen that their maxima appear in the same positions as the lines in Fig. 2*b*; in other words, the *crystal grains have identical spacings*.

Two suggestions may be offered to explain the striking spread of the spots in a case such as that of Fig. 2*a*. In the first place, though the smooth α doublet lines of Fig. 2*b* appear to be well resolved, examination with a microphotometer shows that they are actually so wide that they overlap, showing that $\delta\theta$ is greater than the separation of α_1 and α_2. Thus there may be a complete overlap of the spots due to α_1 and α_2 when the crystal is stationary.

In the second place, if the incident radiation is not monochromatized, Laue spots due to white radiation appear all over the film. Some of these spots may be near the K_a lines, and seem to belong to them, thus increasing the apparent spread.

We wish to stress, however, that it is still an open question whether all the features of Dr. Müller's photographs can be explained in this way; further investigation is required.

Dr. Müller's experiment suggests an elegant way of examining individual crystal grains, for we gain more information about their dimensions from the individual smears of Fig. 2*c* than from the complete rotation illustrated in Fig. 2*b*, which merely gives the average size.

Cooling Curves and the Laws of Radiation

I WISH to record a method of treating the radiation between a body and a surrounding enclosure which has been applied to the study of the heating and cooling curve techniques so much used by metallurgists, and may have other uses.

If the time-temperature relationship of such a body is obtained from the Stefan-Boltzmann law, the resultant expression and equations derived from it, if the case is even slightly complicated, are too difficult to be handled by workers of ordinary mathematical attainments. The use of Newton's law of cooling gives simpler expressions, but leaves an uncertainty as to their validity, particularly for theoretical work. By equating a Newtonian expression of radiation such as $k(T-T_e)$ to the corresponding Stefan expression, the 'constant' may be evaluated: and it is found that in many interesting cases the approximation $k = 4C\sigma T_g^3$ (where C is the area-emissivity coefficient between body and enclosure, σ is the absolute emissivity of a black body, and T_g is a fixed temperature chosen by rules which are often very simple) is a very good one, and that equations based on it are easy to handle. For the case of a thermally simple body in an enclosure the temperature of which is a linear function of time, for example, there is, when t is large, an important temperature difference between specimen and furnace (unsuspected or ignored by many previous workers) given by $\rho = - \dfrac{ms}{4C\sigma T_g^3} \cdot \dfrac{dT_e}{dt}$ and the temperature difference at all values of t is given by $\dfrac{\varphi - \rho}{\varphi_0 - \rho_0} = e^{-4C\sigma T_g^3 t/ms}$ where s is specific heat of the specimen, and φ is $T - T_e$.

This manageable form can be modified to allow for heat transfer other than by radiation, and permits, among other things, the existing thermal curve techniques to be examined in a critical manner. In the course of this it was found that if the enclosure temperature as well as the temperature of the specimen were observed, these techniques would be improved in that certain difficulties of interpretation would be removed, and enriched in that the heat quantities involved in a physical change could be assessed and curves of dH/dT (H is the heat contents of the specimen) obtained, not in many cases with the accuracy of Sykes's method[1], but with complication and labour little greater than that of an ordinary thermal curve, and with the ability to work with both rising and falling temperatures.

Two techniques so suggested appear particularly promising. The first is a modified inverse rate curve method. The values of $\delta t/\delta T$ usually observed, when multiplied by the appropriate values of φ, enable a curve of relative dH/dT to be plotted, and absolute values may be obtained if a suitable constant or constants are determined. Mr. W. S. Walker, formerly demonstrator here, has during the last three years developed the practical side of this method and used it to measure the heat changes in carbon steels over the allotropic range, but publication is delayed owing to an unforeseen experimental error. The second technique involves the concurrent plotting of $T-t$ and T_e-t curves by a semi-automatic device permitting a very open scale to be used. The taking of these curves should be less mentally exacting than obtaining a high-grade inverse-rate curve; they will be fairly sensitive and very easy to interpret, and curves of dH/dT are obtainable by measuring areas between the pair of curves. Mr. E. A. Fowler, assistant lecturer here, is collaborating with me in developing this method.

A critical examination of Plato's[2] and Rosenhain's[3] heat evaluation techniques has been made, and it is hoped to publish this shortly.

Stimulation of Paramagnetic Absorption by a Constant Field

IN previous researches[1] it has been found that paramagnetic absorption at frequencies of about 2×10^7 may decrease considerably under the simultaneous application of a constant magnetic field. We have now observed that, on the contrary, paramagnetic absorption may be strongly stimulated by a comparatively large constant field applied parallel to an alternating field of comparatively low frequency. The accuracy of our observations did not allow us to detect the dissipation of heat in iron alum at a frequency of $3 \cdot 7 \times 10^6$ and a temperature of 77° K. in the absence of a constant field. But under the influence of such a field a strong absorption appeared which attained a maximum at 1,000 oersteds and decreased in still larger fields. The maximum shifts to larger fields for higher temperatures and lower frequencies.

These results are in agreement with our recent observations[2] on paramagnetic dispersion in the same region of frequencies and temperatures, which had already indicated that the absorption region shifted enormously (from about 10^9 to 10^6) under the influence of a strong parallel field. Further, the conclusion[3] that the phenomena at a fixed temperature and field cannot be described by one single relaxation time is corroborated by these results.

Details will be published in *Physica*.

A Wireless Interferometer

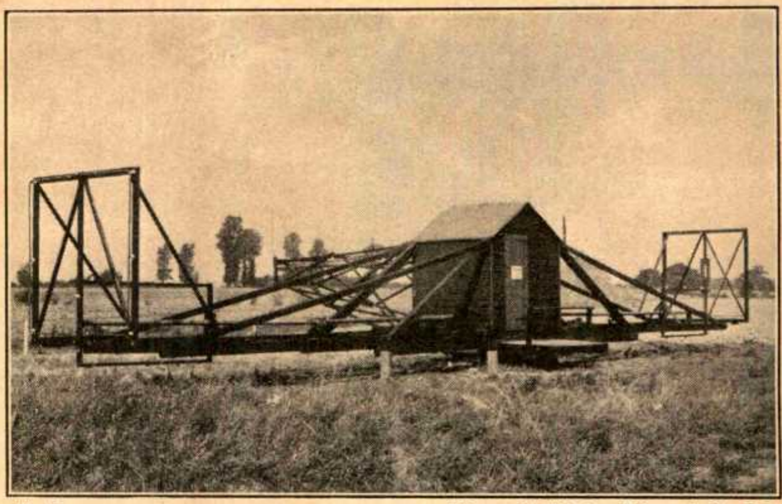
IN a recent communication in NATURE[1], the use of a pair of spaced frame aerials for locating the position of the scattering clouds in the E layer of the ionosphere was described. The system, an example of which is shown in the accompanying illustration, has another function, which is also of importance in the investigation of scattering, namely, the determination of the spread in direction of the scattered rays.

In the presence of a single ray, the E.M.F.'s in the two aerials are definitely related in phase and amplitude, and so it is possible by varying these quantities in the central circuit completely to balance the output of the system. When, however, there are many rays of random direction and phase forming a spread pencil or cone of independent rays, the setting for any one ray differs from that of the others, and all the rays cannot be balanced simultaneously. It is no longer possible to obtain a complete balance since the E.M.F.'s in the two aerials are not exactly correlated. There is a certain random diversity effect which increases as the frames are spaced farther apart. It is possible to calculate the degree of correlation between the E.M.F.'s in the two aerials when it is assumed that the E.M.F. arises from rays of random phase and direction within a cone of angular aperture φ_0, the distribution being

$$Ae^{-\varphi^2/\varphi_0^2}$$

The correlation coefficient r is then approximately

$$r = 1 - \left(\frac{2\pi d}{\lambda} \frac{\varphi_0}{2}\right)^2, \text{ so long as } \left(\frac{2\pi d}{\lambda} \frac{\varphi_0}{2}\right) \leqslant 1.$$



Photo] [*Marconi's Wireless Telegraph Co. Ltd.*

With such a correlation coefficient, it is also possible to calculate the ratio of the residual E.M.F. at the best obtainable balance to the E.M.F. of one aerial alone. This ratio is

$$\frac{u}{v} = \frac{2\pi d}{\lambda} \frac{\varphi_0}{\sqrt{2}}$$

and becomes unity, that is, there is no effective balance at all, when $\pi d\varphi_0/\lambda = 1/\sqrt{2}$.

It will be observed that except for a numerical factor of the order of unity depending on the distribution function of intensity within the pencil of rays, this is exactly the Michelson interferometer formula relating the angular diameter φ_0 of a pencil of rays to the observed mirror spacing d at which the contrast ratio in the fringes disappears. Thus the pair of spaced frames constitutes a wireless Michelson interferometer, the frames taking the place of the mirrors and the ratio u/v corresponding to the fringe intensity ratio.

In the radio technique, the spacing is left constant but the contrast ratio measured. In the astronomical technique, the distance d is varied until the contrast ratio is unity. The same quantity, namely, the angular spread, is, however, measured in both cases.

Observations have been made during the past year to measure the angular spread of the rays reflected from the ionosphere.

Two salient facts emerge: The first is, that whereas for local ground signals balances, that is u/v ratios, of 1/1,000 or less can be obtained, it is very rare for a reflected signal from the ionosphere to give a better balance than about 1/30, with 20-m. frame spacing, and the balance is usually of the order of 1/10, giving a spread of the order of 1° or 2°. The second is that the behaviour of the short scattered echoes (from heights of 100 km.) is in complete contrast with that of the normal echoes from the *E* or *F* layer (indicating a completely different mechanism of reflection). Whereas the latter all give a quite well-defined balance, it is almost impossible with 20 m. spacing to find any balance at all on the former, except on rare occasions. With 6 m. aerial spacing, the balance is broad and ill-defined, with a minimum-maximum ratio of ½ to ⅓ implying angular spreads of the order of 30°. Thus the spaced aerial system, used first as a direction indicator and secondly as an interferometer, indicates, in both cases, that the sporadic short-scatter reflections are of an entirely different character from the normal *E* and *F* reflections. Both the results imply that the sporadic echoes are not reflected from a uniform *E* layer, but from high density patches in the *E* region, which are irregularly distributed both in time and in space.

Spectrum of Chromium Chloride, CrCl

RECENTLY Mesnage[1] has reported a system of bands, degraded to the red, in the region 2600–2650 A. He obtained the bands by an electrodeless high-frequency discharge through a heated quartz tube containing chromium chloride. We have noticed that the wave-lengths recorded agree very closely with those of the known system of aluminium chloride. The wave-lengths given by Mesnage, with their vibrational quantum numbers, are reproduced beside those for the corresponding aluminium chloride bands as observed by Bhaduri and Fowler[2]; the intensities given are those for AlCl, Mesnage not having recorded any intensities for the bands which he observed.

CrCl (Mesnage)		AlCl (Bhaduri and Fowler)	
λ	v',v''	λ	Int.
2638·1	2,4	2638·10	3
2632·9	1,3	2632·80	3
2629·8	0,2	—	
2627·0	1,2	2627·00	3
2623·5	3,2	2623·54	5
2622·3	0,1	2622·40	4
2619·9	1,1	2619·98	4
2618·1	2,1	2618·21	3
2614·3	0,0	2614·44	8
2612·0	1,0	—	
2610·3	2,0	2610·22	6

It will be seen that all except two of the eleven bands agree to within 0·14 A. Of the AlCl bands, all the strongest of those which are degraded to the red are included in the above list; the AlCl bands degraded to shorter wave-lengths in the same region do not appear to have been observed. Jevons[3] has commented on the occurrence of AlCl bands when using aluminium electrodes in discharge tubes, and the bands appear to be of frequent occurrence as an impurity, but it is not easy to see how the bands could arise in an electrodeless discharge, unless perhaps the chromium chloride picked up a chip from the mortar when it was pulverized. In the absence of published photographs of Mesnage's bands, or any estimates of their intensities, it is difficult to be quite certain of the identity of the two systems, but the agreement seems to be much too close to be entirely fortuitous.

The vibrational analysis proposed by Mesnage gives the vibrational constants $\omega_{1/2}'$ and $\omega_{1/2}''$ for the upper and lower electronic states of CrCl as about 33 cm.$^{-1}$ and 117 cm.$^{-1}$ respectively. These values are in any event surprisingly small and can scarcely be correct; judging by the values of these constants for other chlorides, we should expect values of the order 300–400 cm.$^{-1}$ for CrCl.

Lecture-Room Demonstration of Electron-Optical Crystal Patterns

AN electron-optical image of the crystalline pattern of a metal surface in a sealed-off cathode-ray tube was obtained by Schenk[1] for nickel, cæsium metal serving as activator. The optimum of emission was obtained at a temperature of about 500° C.

Some time ago, we succeeded in obtaining similar results for nickel, nickel iron and iron, using strontium and barium as activator. Metallic strips of the first-mentioned metals were mounted as cathodes in vacuum tubes of similar type to that already described[2], in which a tungsten spiral covered with a suspension of strontium carbonate in amyl acetate and a barium evaporator[3] were mounted.

After evacuation and while the tube was still connected with the pumps, the cathode was heated to a fairly high temperature, then strontium (probably together with strontium oxide) was deposited on it by heating the tungsten spiral. Afterwards a quantity of barium was evaporated in order to absorb the gas residue. Although by this procedure the main part of the evaporated barium was deposited on the wall of the tube, part of it was deposited on the cathode, the latter thus being probably activated by both strontium and barium. Finally the tubes were sealed off.

With an 'electron-microscope' of this type (using a magnetic focusing coil as described elsewhere), intensive emission patterns could be obtained after a (not always identical) heat treatment of the cathode. With nickel and nickel-iron, the intensity of the emission after suitable activation at a temperature of the cathode of about 700°–800° C. was such that the fluorescent pattern could be projected optically on a screen (for example, 50 cm. × 50 cm.), thus giving rise to a highly magnified image of the crystal pattern of the metal surface, visible in a lecture-room[4].

Seismic Waves in the Core of the Earth

THE velocity of longitudinal waves in the earth increases with depth down to the core, at a depth of about 2,900 km., where there is a discontinuous drop from 13·7 km. to about 8 km. per sec. Within the core, the velocity has usually been calculated as increasing gradually to about 11·5 km. per sec. at the centre.

This velocity distribution leads to a well-known focusing effect for longitudinal waves which have passed through both mantle and core (*P′* waves), at about 142° from the epicentre. The interval between this focus and the last arrival of direct longitudinal waves through the mantle (*P*), at about 105°, should be a shadow zone. The *P* waves are known to continue into this interval by diffraction around the core. Apparently, the *P′* waves also extend backward into the shadow zone from 142° to about 110°. These observations have been referred to diffracted *P′* waves, although the process of such a diffraction is very obscure. The large amplitudes of these waves, especially about 122° and 111°, strongly suggest that another explanation is needed. Supposing that these are also direct waves through the core, we find that all observed travel times and amplitudes are consistent with a velocity in the core increasing from 8 km./sec. at its surface (depth 2,900 km.) to about 10·2 km./sec. at 4,850 km., where a rapid but probably continuous increase takes place, the velocity reaching 11·4 km. per sec. at 5,150 km., then decreasing very slowly to 11·3 km./sec. in the central part of the core.

This velocity distribution requires two additional reversals in the travel time curve, which accounts for various peculiarities in the observations of *P′* near the focal distance (which remains unchanged at 142°). It also accounts for similar observations of other waves, such as *SKP* and *P′P′*.

Effect of Veiling Glare on Apparent Size and Distance

THE effects of the veiling glare due to illuminated fog may be imitated by reflecting diffused light into the eye from a piece of plate-glass at 45° to the line of vision. The intensity of the glare may be varied readily, but remains unchanged relatively for objects seen at different distances through the glass plate. In this it differs essentially from the glare of fog, which may be greater for distant than for near objects.

The relative apparent sizes of two similar disks seen at different distances in normal vision do not depend simply on the inverse square law, but on the index of 'phenomenal regression'[1] peculiar to each individual subject of the experiment. When two such disks, or other objects, are seen through a veiling glare, the 'articulation' of the visual field is reduced by the glare, and the influence of distance cues is cut out to some extent. We have found, in an experiment done at the University of Glasgow, that, when glare is present, the relative apparent sizes of similar disks at different distances approximate to the sizes expected on the inverse square law. As the glare increases, this approximation increases too, until, with monocular vision and glare such that all distance cues are cut out, it is very close indeed. Glare appears to be the only factor which has such a marked effect on phenomenal regression. With monocular vision under fullest glare, however, one subject out of seven saw the distant disk the same size as the near disk when the near disk was about three times the diameter expected on the inverse square law—even larger than in binocular vision without glare.

The full report on this experiment will be published in the *British Journal of Psychology*, but we should like to point out that it is of great interest in relation to the problems of vision under fog and glare conditions in everyday life. It should be possible to get a more satisfactory imitation of fog glare by an apparatus in which differential glare could be made for the objects of which the sizes or distances are compared. The problems centre around apparent distance as well as apparent size. It is well known that in fog objects seem unexpectedly large, and this is believed to be due partly to the increase in their apparent distance. Artists habitually avoid showing detail in objects which are to seem distant, and the increase in apparent distance of objects seen in fog is partly due to the blurring of detail and partly to the reduction of distance cues in the surrounding visual field. Experiments could be devised in which apparent distance varies, and in which the objects compared have some visible structure which would be blurred by the glare.

Only one subject out of seven who did the experiment at Glasgow confirmed, under the conditions of that particular experiment, the common observation that distant objects look large in fog, and, in general, the results indicate that great individual differences are to be expected. Individual differences in phenomenal regression probably affect the relative accuracy of different people in comparison of sizes, distances and speeds under normal conditions, but it is likely that the man with the highest phenomenal regression will be most disturbed by fog.

These and other points could be investigated experimentally, and might be of great interest in relation to the problems of the control of motor-vehicles, aeroplanes, ships, and also of the accuracy of aiming and shooting, under glare, fog, or in twilight vision.

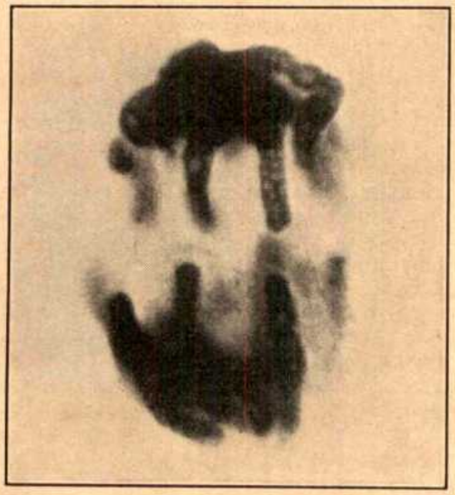
Structure of Chromosomes

PROF. RUGGLES GATES has published photographs of chromosomes at mitosis in *Trillium sessile* by Mr. Mensinkai, which he states show a double coiled structure of chromatids[1]. It happens that structures of this kind have also been obtained in the John Innes laboratory in root tip preparations of the same species and are described in an article by my colleague Mr. La Cour and me in a paper now in the press[2].

It is generally recognized that the fixative employed may influence the products of fixation observed in the cell. Our paper deals with the comparative effects of various fixatives in current use, and we found that the appearance of two threads was an artefact induced by the fixative and due to bubbles of different refractive index in the chromatid. In our experiments these were shown clearly when a fixative containing a high proportion of acetic acid (alcohol acetic, Flemming with acetic) was used. They were practically absent when the acetic was omitted in Flemming solution. Prof. Gates does not state what fixative was employed by Mr. Mensinkai. It will be seen in Mr. Mensinkai's photographs (as in the accompanying figure) that the bubbles are of different sizes, and the single line may be broken by two lying side by side. This would imply, in parts at all events, a triple thread. Prof. Gates concludes that the chromatid is double or even quadruple; is he prepared to admit that it may be triple? Until Prof. Gates can establish the fact that the structures observed by Mr. Mensinkai are real properties of the chromatid itself and not effects induced by the fixation, it would be idle for me to discuss their problematical bearing upon my hypotheses of chromosome structure and the relation of meiosis to mitosis.



Trillium sessile, ROOT TIP SMEAR FIXED MEDIUM FLEMMING + ACETIC, STAINED FEULGEN. × c. 1600.

Prof. Gates also rejects specifically the evidence of X-ray changes in the chromosomes. The genetical experiments on these lines by Morgan and his collaborators[3] and the cytological experiments by Riley[4] and Mather[5] have not to my knowledge been disputed by anyone but Prof. Gates. Elsewhere[6], Prof. Gates has similarly rejected the evidence of the chromomere at meiosis and in the salivary glands of Diptera. If the observations of Belling and Belar and of Heitz and Painter are thus disposed of, I am content that my views should place me rejected in their company.

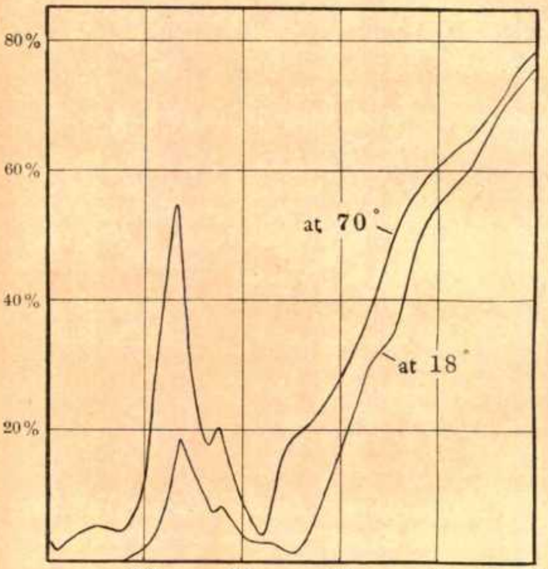
Hydroxyl Frequency in Carboxylic Acids

THE recent work of Errera and Mollet[1], Fox and Martin[2] and others has shown how the association of single molecules of the alcohols may be studied by means of their infra-red absorption spectra, more particularly in the region of the 'O—H' fundamental frequency and its overtones. In the course of an investigation (suggested by Prof. E. K. Rideal) of the inter- and intra-molecular interactions of the hydroxyl (OH) and carboxyl (COOH) groups in solutions of the ω-hydroxycarboxylic acids, we have been making a preliminary study of the infra-red absorption of some of the simpler carboxylic acids in solution and have established the existence of a similar phenomenon for association of these acids. Although indications of this have already been apparent from the work of Gillette and Daniels[3] on the shift of the 'C=O' and 'C—O' frequencies during association, and from that of Badger and Bauer[4] on a presumed overtone of the 'O—H' frequency in the photographic region, the effect of association on the fundamental 'O—H' vibration would appear to have been missed. Yet here the effect may best be studied and presents (as we have found) several interesting contrasts to the case of pure hydroxyl interaction in the alcohols.



Our results are best described by reference to the accompanying graph, which shows the absorption of a 0·0167 molar solution of benzoic acid in carbon tetrachloride at temperatures of 18° C. and 75° C. It will be seen that at ordinary temperatures there is a very weak band at $2 \cdot 837 \pm 0 \cdot 003\,\mu$, which greatly increases in intensity on raising the temperature. This corresponds exactly to the behaviour of the $2 \cdot 76\,\mu$ band of the alcohols, indicating the formation of a greater concentration of the monomeric molecules at the higher temperature. The shift in the position of the characteristic OH absorption from $2 \cdot 76\,\mu$ to $2 \cdot 84\,\mu$ is of particular interest in distinguishing the OH group in a carboxylic acid from the OH group in an alcohol.

Acetic acid gave results exactly similar to the above, but an investigation of trichloracetic acid was more interesting in that the monomeric OH frequency was shifted to $2 \cdot 860 \pm 0 \cdot 003\,\mu$. This indication of a slightly weaker OH bond presumably corresponds to its behaviour as a much stronger acid than acetic. We have also found that the apparent gradual shift in the 'C=O' frequency at 5·8 μ observed by Gillette and Daniels is really due to there being two separate bands, one coming from the monomer and the other from the dimer.

Another important result from the examination of trichloracetic acid was the discovery of an extremely broad absorption band near 3·3 μ, the intensity of which decreased with rise of temperature. It is difficult to see how this can be anything other than an "association band" corresponding to that in the alcohols at about 2·95 μ.

It should be added that the variation in the monomeric OH band was also achieved by varying the concentration of the acid in the solvent and measuring the integral absorption. The possibility of determining the heat of association of the acid in solution from the integrated absorption curves at different temperatures is being investigated.

Separation of the Glucolytic Enzyme System from the Brain Cells and its Coenzymes

Numerous attempts have been made in the past, with little success, to separate the glucose-splitting enzyme system from brain cells[1,2,3]. The most active extract obtained hitherto had less than 1/20 of the activity of the original tissue[3].

Table 1

	Lactic acid formed by 10 ml extract (corresponding to 2 gm. brain) in 1 hr. from glucose	from glycogen
Brain extract alone	0·22 mgm.	0·24 mgm.
„ „ and boiled yeast extract	0·56 „	4·44 „
„ „ „ „ „ and *Co–Z*	4·21 „	7·22 „
„ „ „ „ „ „ and *Ap*	4·28 „	7·78 „
„ „ „ „ „ „ „ and *GSH*	6·28 „	7·91 „
„ „ „ „ „ „ „ „ and *Cr–P*	24·68 „	7·85 „
„ „ and all the former activators without yeast extract	0·72 „	1·04 „
2 gm brain pulp ground in Ringer sol. and all activators added	12·24 „	1·05 „

No lactic acid was formed by brain extract from substances contained in boiled yeast extracts.

A cell-free brain extract has been prepared with about twice the glucolytic activity of intact brain cells. On cytolysis, a potent inhibitor of glycolysis is liberated from brain. This inhibitor, which is probably an enzyme, does not pass into the extracts if the extraction is carried out in slightly acid medium (*p*H 5·5–6·0). Such an extract contains the glycolytic system but no inhibitor. It has a very slight glucolytic activity. By the addition of suitable activators or coenzymes, however, the glucolytic activity of this extract may be increased up to 2–3 times that of intact brain cells.

One of the coenzymes—the nature of which is yet unknown—is contained in boiled extracts of beer-yeast, in boiled muscle extracts and, in small amount, in boiled extracts of brain. Creatinephosphate was found to be a specific coenzyme of the glucose-splitting enzyme system. Glutathione and cozymase are also required for full activation.

Lactic acid is also formed by brain extracts from glycogen on addition of boiled yeast extract, adenosinetriphosphate and cozymase. About three times more lactic acid is formed from glucose than from glycogen. Creatinephosphate has no activating effect on lactic acid formation from glycogen, although it strongly activates lactic acid formation from glucose.

The extracts are made by grinding one part of rat brain with three parts of ice-cold distilled water and one part of 0·1 *M*. phosphate solution of *p*H 5·5–6·0. After standing on ice ten minutes, the suspension is centrifuged. Air-dried beer-yeast is extracted with three parts of water. The centrifuged yeast extract is heated in boiling water for three minutes.

Table 2.

	From glucose lactic acid	From glucose P_2O_5	From glycogen lactic acid	From glycogen P_2O_5
	mgm	mgm	mgm.	mgm
Start	—	3·92	—	4·14
15 min. at 37° C.	0·42	3·77	0·22	4·01
35 „ „ „	1·05	3·56	0·44	3·96
70 „ „ „	2·57	3·14	1·12	3·87

The experiments described here were made by mixing 2 ml. of brain extract with 1 ml. of boiled yeast extract and making it up with the additions to 6 ml. Activators were added in the following amounts: 2 mgm. adenosinetriphosphate (*Ap*), 3 mgm. creatinephosphate (*Cr–P*), 2 mgm. glutathione (*GSH*), 1 mgm. cozymase (*Co–Z*). 1 ml. of brain extract corresponds to 0·2 gm. fresh brain.

The same amount of lactic acid is formed from glucose alone as from glucose and glycogen when both are added to the same flask. In one experiment, for example, 3·27 mgm. lactic acid was formed from glucose alone, 1·05 mgm. from glycogen and 3·19 mgm. in a flask where both were added together. It seems, therefore, that the glucolytic and the glycogenolytic enzyme systems in brain, though different, probably have common components.

Inorganic phosphate (or creatinephosphate) is esterified in brain extracts during glycolysis as shown in Table 2. (Inorganic phosphate includes creatinephosphate.)

The experiments described above indicate that the observations made on intact brain cells are not valid for cell-free extracts.

Full details will be published elsewhere.

Mechanism of the Biological Synthesis of Acetylcholine

Stedman and Stedman have stated in a recent issue of NATURE[1] that the presence of acetoacetate leads to acetylcholine synthesis in the brain. The evidence for this conclusion is apparently the fact that the rate of acetylcholine formation by brain tissue macerated in the presence of chloroform and eserine and incubated at 37° is increased on the addition of sodium acetoacetate to the macerate.

Such evidence by itself seems to us quite insufficient to justify the conclusion that acetoacetate takes part directly in acetylcholine synthesis. In the first place, we have found that the rate of acetylcholine formation by ox brain tissue, treated in the manner adopted by the Stedmans, is greater at 18° (room temperature) than at 37°. In fact, this so-called synthesis of acetylcholine is no less at 0° than at 37°. Acetylcholine production by chloroform-treated brain in the absence of added acetoacetate at 18° is greater than that which occurs at 37° in the presence of acetoacetate. At 45° the apparent synthetic action of acetoacetate in the presence of whole ox brain is marked (even exceeding the 100 per cent increase claimed by the Stedmans to take place chiefly with the basal ganglia) but the greatest rate of acetylcholine formation found at this temperature in the presence of acetoacetate is less than that which occurs at room temperature in the absence of acetoacetate. At room temperature where, under the Stedmans' conditions, there is considerable formation of acetylcholine, the addition of acetoacetate has little or no effect.

We have further found that, under conditions approximating as closely to the physiological as possible, substances such as glucose, sodium lactate and sodium pyruvate effect rates of synthesis of acetylcholine in brain tissue which are six to ten times that which take place when such substrates are not added[2]. Yet under these optimal conditions for acetylcholine synthesis in the brain, the addition of sodium acetoacetate has little or no effect on the synthesis.

It seems to us that the acetoacetate effect noted by the Stedmans is connected with the peculiar conditions under which their experiments are carried out. Maceration of brain tissue with chloroform in the presence of eserine, and incubation of this in the absence of buffer solutions or physiological media at 37° under semi-anaerobic conditions, certainly leads to free acetylcholine formation, but the mechanism of this formation requires elucidation. Until this elucidation has been obtained it seems to us rash to conclude, if a given substrate increases the rate of formation of acetylcholine, that this substance necessarily takes part in the synthesis of acetylcholine. Our own results lead us to believe that the action of chloroform on minced brain tissue is greatly to accelerate the breakdown of a complex precursor into free acetylcholine. We consider it likely that the Stedmans' results are connected not with a true synthesis of acetylcholine but with the breakdown of a precursor preformed in the brain tissue. Conceivably, under the conditions obtaining in the Stedmans' experiments, acetoacetate and other substances may affect the velocity of breakdown of the precursor.

It is difficult to compare the results of our experiments with those of Stedman and Stedman since the conditions under which they are carried out are so very different. But under our conditions, which very much more closely approach the physiological, there is as yet no evidence for the conclusion that acetoacetate is directly concerned with acetylcholine synthesis.

Our results and conclusions on the mode of synthesis of acetylcholine have already been communicated to the Physiological Society and will shortly be published in the *Biochemical Journal.*

Ethnographical Museums

THE student of ancient civilizations, who knows how much of the raw material of history is to be found in our museums, will be grateful to NATURE for the leading article in the issue of January 29 on the purpose and function of ethnographic collections.

The critics of the India Museum in South Kensington, some of whom are apparently prepared to view with equanimity the dispersal of the present collection, will have served a useful purpose if they have directed attention to the interesting experiment in arrangement which is being made under the present keeper, to whom a well-deserved tribute is paid in the article. Those readers of NATURE who are familiar with the report of the Museums Association on the museums of India, and who know from its contents how many collections of antiquities in India have defied arrangement and continue to defy examination by the specialist and student, will best be able to judge how much has been done for the study of Indian civilization by the authorities responsible for our own museum in London. The detailed accounts of Indian history and mythology that accompany the exhibits are a model of what such things ought to be. Indeed, the masterly sketch of the influence of classical art in India on the wall next to the exhibition of the recently acquired sculptures from Hudda in the entrance hall is one that even the specialist may ponder with profit.

The amalgamation of the Indian collections in South Kensington and in the British Museum would provide in London a permanent centre for the study of Indian history and Indian art, which would have no equal in Europe. The advocates of an Indian exhibition, as a step towards the solution of this problem, will command less support from students and scholars. It is appropriate to ask whether those enthusiasts for cultural relations who recommend a temporary Indian occupation of Burlington House, London, have carefully considered what they propose to exhibit. The Ajanta caves cannot be brought to the Royal Academy, nor the gateway of the Sanchi Stupa (a plaster copy of which towers over the staircase in South Kensington), nor, for that matter, the remains that still lie buried under the soil of India and of neighbouring countries, awaiting the spade of the archæologist. A mere exhibition of arts and crafts would involve just that divorce between art and life which, as is pointed out, is such a disservice to the student of any civilization. It is precisely because the authorities who are now responsible for the Indian Museum have not confused the function of a museum with that of an art gallery, that wide support should be given to any proposal to bring together the various Indian collections in London under one roof and under their control.

Realistic Social Studies

I DID not see the leading article on "Realistic Social Studies" in NATURE of January 22 until more than a fortnight after its publication, when it seemed already too late to offer any comments on it. As, however, NATURE of February 12 contains a further reference to this article and to the London School of Economics and Political Science, of which I was until recently director, I hope I may be allowed to make some comments now, registering disagreement on two points and agreement on one.

My first disagreement is with the statement in the NATURE article that I graduated in astronomy. It is true that at one time I aspired to be an astronomer, and, with that in view, studied mathematics for my first year at Oxford. But at the end of that year I became convinced that I was not a mathematician, and less rightly that there was nothing more to be discovered in astronomy.

My second disagreement is with the suggestion, which perhaps was not intended but which appears to arise out of the article, that the Rockefeller Foundation declined to renew a grant to the School of Economics because of some special dissatisfaction with the economic teaching and research of that institution. It is a matter of common knowledge that at the end of 1934 the Rockefeller Foundation adopted a new policy in regard to the social sciences generally. This policy excluded the indefinite continuance of any grants similar to those which had been made for several years by the Foundation to the School, but, subject to this, it is, I think, fair to say that the Foundation treated the School with exceptionally friendly consideration rather than the reverse. The new policy involved termination of grants to many institutions all over the world. The temporary renewal on a tapering basis of the grant to the School, which was due to terminate immediately after the adoption of the new policy, was not a blow at the School, but a piece of special consideration for it.

My third point, of agreement, is with the view implicit in the NATURE article that progress in the social sciences depends upon their coming nearer to the natural sciences in methods and spirit. This I take to be the main point of the article, as it was the theme of my address on "The Place of the Social Sciences in Human Knowledge", of which a summary was published in NATURE of June 26, 1937 (139, 1117).

Points from Foregoing Letters

Prof. W. L. Bragg and H. Lipson consider that the scattered spots observed by Dr. Muller in X-ray crystal photographs taken at an angle of nearly 90° for the incident rays—from which he had deduced comparatively wide lattice variations in individual crystals—may be due to the angular range of the diffraction of the radiation after specular reflection at each crystal plane, the small crystals being variously oriented. To test this view, they have rotated the crystalline specimen (copper wire) through an angle of 3° while exposed to X-rays, and find that the maxima of the intensities of the spots—now elongated into 'smears'—are not 'staggered', but fall into place below each other. This, they consider, proves that the crystal grains have identical spacings.

The paramagnetic absorption in iron alum is found by F. Brons and Dr. C. J. Gorter to be strongly stimulated at a frequency of $3 \cdot 7 \times 10^6$ and a temperature of 77° K. in the presence of a comparatively large constant field applied parallel to the alternating field. Absorption attains a maximum at 1,000 oersted.

A pair of spaced frame aerials can be used to determine the spread in direction of the rays scattered by reflection from the ionized *E* layer of the atmosphere, according to experiments by T. L. Eckersley. The apparatus described indicates that the observed sporadic echoes are reflected from high density patches in the *E* region, which are irregularly distributed both in time and in space.

It is pointed out by Drs. A. G. Gaydon and R. W. B. Pearse that the band spectrum observed by Mesnage and attributed to chromium chloride agrees closely with the already known spectrum of aluminium chloride.

To explain the registration, in the 'shadow zone', of the *P′*-earthquake waves—Prof. B. Gutenberg and C. F. Richter postulate that the velocity of the waves in the earth's core increases from 8 km./sec. at its surface (depth 2,900 km.) to 11·4 km./sec. at 5,150 km., and then decreases slightly to 11·3 km. in the central part of the core.

T. M. Martin and Dr. R. W. Pickford find that in the presence of 'glare'—such as produced by illuminated fog or by reflection of diffused light into the eye by a plate-glass at 45°—the relative apparent size of a disc at different distances is much nearer to what would be expected from the inverse square law than is the case under normal conditions. This may be attributed to the absence of 'distance cues' when the glare is strong.

A cell-free brain extract with about twice the glucolytic activity of the intact brain cells has been prepared by A. Geiger by carrying out the extraction in slightly acid media. The addition of coenzymes (found in extracts of beer-yeast, boiled muscle, etc.) is necessary and glutathione and cozymase are also needed for full activation.

Experiments on the formation of free acetylcholine by brain tissue macerated in the presence of chloroform lead Drs. P. J. G. Mann, M. Tennenbaum and J. H. Quastel to the view that the chloroform accelerates the breakdown of a complex precursor into free acetylcholine and this increases the rate of formation of acetylcholine. They throw doubt on the mechanism suggested by Stedman and Stedman who assumed that the presence of acetoacetate leads to acetylcholine synthesis in the brain.

Research Items

War and Morality among the Ngoni

THE interrelation of the moral code and the character of the community and its demands on the individual are considered by Dr. Margaret Read in a study of the moral code of the Ngoni of Central Africa in relation to their former military state (*Africa*, 11, 1; 1938). Before the coming of the Europeans, the Ngoni were a nation under arms, to whom war had been in the first instance the means by which they maintained their right to settlement in a new country, and afterwards to extend their territory and acquire cattle. It was also, however, as affecting the individual, a moral training ground by which certain moral qualities were inculcated, especially after puberty, and by which they were taught that strength and bravery were not a momentary flash in times of stress, but the outcome of training and discipline and a clear conscience. If a man had committed adultery before going to war, he was 'afraid in his heart' lest he should play the coward. If a regiment failed to carry out its task, the cause was assumed to be some moral lapse. Apart from the conditions of war, the traditional sanctions were directed to preserving the solidarity of the State and to maintaining aristocratic traditions. The preservation of these traditions rested with the women of good family. The moral code, which was inculcated from infancy to puberty and marriage, and afterwards regulated the conduct of married life, was rigidly enforced in the interests of the community. Upon its observance depended the internal security of the State and the success of its arms in war. The situation to-day as regards sexual morality is deplored by the Christian and non-Christian Ngoni alike. They attribute it to the coming of the Europeans, which has torn up by the roots the sexual morality, which was so closely bound up with the needs of the community. The chiefs could no longer exercise control over the lives of their subjects, while the prohibition of war involved abolishing the regiments with their discipline and training.

The Desert Locust in Arabia

R. C. MAXWELL-DARLING has recently published an article on the outbreak areas of the desert locust (*Schistocerca gregaria*) in Arabia (*Bull. Entomol. Res.*, 28, 605; 1937). In his capacity as locust investigator of the Imperial Institute of Entomology, the author undertook journeys in southern Arabia with the view of ascertaining whether there is likelihood of outbreak centres existing in that area. As the result of several years' work in the Anglo-Egyptian Sudan, Mr. Maxwell-Darling concluded that the only centres of outbreak of this locust in North East Africa lay on the Red Sea coast. This did not, however, rule out possibilities of such centres occurring in Arabia. As the result of 12 months' travel in the latter country, he concludes that the south part of the Red Sea coast and probably that of Yemen are outbreak areas. Concerning other areas, less definite conclusions were arrived at and, as the author points out, if the outbreak areas are properly defined and given the requisite organization, there is every hope that the desert locust might be destroyed before spreading beyond these areas. Large regions have been found to be purely invasion areas, in which outbreaks cannot originate, and only certain restricted areas have been proved to comprise outbreak centres. It has been shown that outbreaks of the desert locust can be suppressed at their source by timely application of poisoned baits. Such outbreaks were prevented, for example, in the Tokar district of the Sudan, during three successive years by the district commissioner and his staff.

Western Indian Ocean as a Faunal Unit

FURTHER evidence that the western Indian Ocean might be regarded as a faunal unit is offered by Dr. K. H. Barnard in his study of the Amphipoda of the recent John Murray Expedition (Scientific Reports, 4, No. 6; 1937). The collection was not a large one, comprising only 116 species, almost all being well-known forms, but they provide useful zoo-geographical information for an area the amphipod fauna of which has remained hitherto practically unworked. That many of these Indian Ocean species extend along the east coast of Africa as far as the southern point of the continent is explained by Dr. Barnard as being due to the Mozambique-Agulhas current. Three problematical species which turned up in the material were *Karoga megalops*, *Sympleustes grandimanus* and *Thoriella islandica*, the first-named of which is known only from Iceland and Alaska in deep water, while the others are deep-water Atlantic forms. Dr. Barnard asks whether it is "too unreasonable to regard these deep-water forms from the Arabian Sea as relics of the Cretaceo-Tertiary Sea of Tethys". He mentions that Lieut.-Colonel Seymour Sewell had also previously found two or three species of arctic copepods in Indian waters.

Meteorology in Egypt

A VERY detailed study of wind, temperature and lapse-rate of temperature in the first sixty-one metres above the ground at Ismailia, on the shores of Lake Timsah, in Egypt, is contained in Geophysical Memoir No. 71, of the Meteorological Office, by W. D. Flower. The observations extend over a period a few days longer than twelve months, but in a climate of such a steady type this period is long enough for bringing out the essential diurnal and seasonal variations of these quantities. The thermal observations include continuous records of air temperature as registered by a platinum resistance thermometer at a height of 1·1 metres and of temperature differences between that height and a height of 16·2 metres, between 16·2 m. and 46·4 m., and between 46·4 m. and 61·0 m. A wind vane and a Robinson anemometer were mounted at the top of the latticed steel tower that carried the thermometers; in addition, there was a Dines pressure tube anemometer several hundred metres away from the tower, with its vane at a height of 15·2 m., and various thermometers of ordinary pattern much nearer to the ground. The analysis of this observational material has been carried out in the most thorough manner, in relation to season, type of sky, strength of wind, situation as regards the synoptic chart for the Mediterranean and neighbouring countries, etc. The results obtained are so many and of such equal interest that it is impossible to summarize them in a short note. This memoir will be a happy hunting ground for students of dynamical meteorology who have theories to test, and above all for those especially interested in terrestrial and atmospheric radiation, for both the inward radiation from the sun and the terrestrial radiation from the ground act powerfully upon the atmosphere in turn each day, under a sky that is very rarely overcast, and yet there is enough water vapour to lead to fog and low cloud at times just before sunrise, and well-marked thermal effects can sometimes be traced to the radiation and absorption of this suspended water and water-vapour.

Use of Pulverized Fuel in Cylindrical Boilers

DURING the last few years, the Fuel Research Station's programme of experimental work on pulverized fuel has included a great deal of research on the use of this fuel in cylindrical boilers. Mr. T. F. Hurley has undertaken to present to the Institute of Fuel a series of papers dealing with results obtained at the Station. His first paper, read to the Institute on December 7, goes far to quash the prevalent idea that powdered coal cannot be successfully applied to Lancashire boilers owing to the smallness of combustion space available as compared with water-tube boilers. In the case of water-tube boilers it is impracticable to reduce the size of combustion chambers owing to the tendency for molten ash particles to be carried out of the furnace. In the case of Lancashire boilers, however, the ratio of boiler heating surface to furnace volume is far higher than that of water-tube boilers. Thus a correspondingly greater heat release can be obtained without molten ash being carried out of the furnace. In this type of boiler, therefore, heat releases are governed primarily by combustion conditions. Admittedly, the high surface to volume ratio is not conducive to good combustion, but reasonably good results can be obtained by suitable methods of rapid ignition followed by rapid combustion. Vindication of the Lancashire boiler fired with powdered coal is substantiated by actual test figures which prove that it can be operated at loads far in excess of those normally obtained.

Cosmic Evolution

PART 5 of vol. 146 of Division 2a of the *Sitzungsberichte* of the Academy of Sciences of Vienna contains a paper on "The Evolution of a Cosmic Dust Cloud" by Prof. Hildebrand. He assumes the cloud to have initially the simplest properties which admit of dynamical treatment, that is, its density is uniform throughout and it is spherical in shape. Each particle is describing an ellipse with a natural period proportional to the 3/2th power of its distance from the centre of the sphere and inversely proportional to the square root of the mass of dust within that distance from the centre. The plane of the ellipse and the direction of motion round it are distributed at random. Impacts between the particles are taken as inelastic. Under these conditions the author shows that impacts will produce mass conglomeration and a tendency for the augmented mass to move in paths nearer the centre of the cloud than before the impact. This increases the central field of force and the central tendency is augmented. In addition the concentrated masses tend without impacts to carry with them an atmosphere of smaller dust. The planes of motion of the masses which effect the primary concentration about the centre determine the "invariable plane" of Laplace, the direction of motion in that plane, and the tendency of the cloud to assume the disk form. This, the author points out, is the first step towards the production of a central system such as the solar system. He proposes to deal in a later paper with the consequences of the heat developed by the non-elastic impacts which he postulates.

Radial Velocities of Cepheid Variables

AN important addition to our knowledge of Cepheid variables has been made by Prof. A. H. Joy (*Astrophys. J.*, 86, 363) who has made a series of velocity observations of 128 stars of this class. Our previous knowledge of Cepheid velocity curves was confined to 29 stars which had been measured frequently and were known with considerable accuracy. Joy has abandoned the practice of intensive observations of selected stars, and attempted a general survey of the fainter Cepheids, using the minimum number of observations of each which would give a reasonable approximation to its velocity curve. Using low-dispersion spectrographs he has been able to extend observations to stars of magnitude 14, and now, in declinations north of −40°, only 35 Cepheids are left for which no observations are available. These are mostly fainter than the fourteenth magnitude. Full details of the individual measures are given, together with diagrams of the velocity curves of 106 stars and a table showing the various data available for 155 Cepheids as deduced from the present observations and including previously published results. A short discussion of the relationships between period and certain characteristic properties of the stars is also given in the light of this extensive new material.

The System of α Ursæ Majoris

THIS is the title of a paper (*Mon. Not. Roy. Astro. Soc.*, 98, 2 ; December 1937) by Dr. H. Spencer Jones and Mr. H. H. Furner. The duplicity of the star was discovered by Burnham in 1889, the separation being then 0″·9, but this had decreased to 0″·6 in 1902, and after this the companion was not seen until 1933. The paper contains a very full description of the meridian observations made at Greenwich and also of the double star observations, as well as a summary of the radial velocity measures made at Lick Observatory. Combining the results, the orbital elements and the mass of each component are deduced. Taking the mass of the sun as unit, the masses of the brighter star and its companion are 2·14 and 0·96 respectively, but a serious discrepancy arises when the mass-luminosity relationship is utilized to find these masses. Use is made of the tables in Eddington's "Internal Constitution of Stars", and it is shown that agreement is reached by the masses derived by this method and from the orbital elements when the parallax is 0″·022. The masses of the components are 8·6 and 3·8 and the velocity of the centre of gravity of the system is − 8·72 km./sec. If the elements so derived are correct, it is difficult to explain the fact that the companion was not seen between 1905 and 1933, as the separation would have been sufficient then for its detection. It is suggested that there may be variation in its brightness, and it may be recorded that a similar hypothesis for the companion of Procyon is the only explanation of the failure to see it from 1914 onwards. Further observations of the α Ursæ Majoris system are highly desirable.

Pithecanthropus and *Sinanthropus*

By Prof. Franz Weidenreich, Cenozoic Research Laboratory, Peiping Union Medical College

DR. R. VON KOENIGSWALD in No. 5147, vol. 191, of the *Illustrated London News* (December 11, 1937) gave an account of the discovery of another *Pithecanthropus* skull in Java and a lower jaw fragment which he also attributes to *Pithecanthropus*. As emphasized in the introductory note by Sir Arthur Keith, these discoveries are of the utmost importance to our knowledge of the history of early man. All students interested in palæoanthropology will, I am certain, appreciate Dr. von Koenigswald's enthusiasm and eagerness in the search for traces of the Java hominids, an undertaking which has now met with remarkable success.

A controversy of many years' standing has suddenly been brought to an end. It may now be considered a certainty that *Pithecanthropus* is not a giant gibbon but a genuine hominid, a fact already demonstrated by Weinert's reconstruction of *Pithecanthropus* Skull I and by the discovery of *Sinanthropus*. In a recent article[1], I have been able to demonstrate that *Sinanthropus* Skull II of Locus *L*, recovered in November 1936, completely conforms in relation between height and length and in other details to the *Pithecanthropus* cap. The more pronounced flatness of the forehead is compensated by a stronger depression in the obelion and lambda region of the former. The new and more complete *Pithecanthropus* skull, which is the very image of the first, confirms this statement. Since the entire temporal bone is preserved, the absolute height of the brain case can be defined and thus permits calculation of the height-length index. This index is the same as in *Sinanthropus* Skull II of Locus *L*; as a matter of fact, it is even somewhat higher than in the latter. The close relationship between *Pithecanthropus* and *Sinanthropus* can no longer be doubted.

With respect to the special nature of the relationship, however, I regret to say that I am unable to accept von Koenigswald's conclusions. He considers *Pithecanthropus* to be more primitive than *Sinanthropus*. This claim is based upon two points: namely, upon the cranial capacity of *Pithecanthropus*, which he estimates to be only 750 c.c. and thus rather inferior to that of *Sinanthropus*, and upon the complete absence of the mastoid process. I doubt the correctness of the first statement. According to the photographs, the greatest length of *Pithecanthropus* Skull II is the same as that of Skull I (about 180 mm.), the greatest breadth (about 140 mm.) only 4 mm. less than that of *Sinanthropus* Skull *E*, and the auricular-bregma-height 95 mm. (against 93 mm. in *Sinanthropus* Skull *E*). The cranial capacity of *Sinanthropus* Skull *E*, however, amounts to 915 c.c. according to exact measurements of the endocast. Unless we consider that the bones of the *Pithecanthropus* Skull II are considerably thicker than the already exceptionally thick bones of *Sinanthropus* Skull *E*—a rather unlikely feature according to von Koenigswald's photographs, especially if the skull is considered to represent a female individual as is surmised by him—it is impossible that the cranial capacity of that skull could be inferior by as much as 165 c.c. According to my own estimation, the cranial capacity cannot be less than 850 c.c. With such a low cranial capacity, *Pithecanthropus* still falls within the range of variation of *Sinanthropus*, for Skull I, recently described[2], certainly did not exceed the 850 c.c. limit. The fragments of the frontal and temporal bones of this *Sinanthropus* skull are considerably smaller than the corresponding parts of the *Pithecanthropus* Skull II. The smallness (complete absence ?) of the mastoid process cannot be considered a standard feature of primitiveness as is suggested by Koenigswald. *Sinanthropus* also shows a very great variability in the size of this protuberance. This process in the Krapina skull is exceptionally small, while in the Rhodesia skull it is as well developed as in recent man.

On the other hand, it should not be overlooked that all *Sinanthropus* skulls exhibit one real primitive feature which is completely lacking in both of the *Pithecanthropus* skulls, namely, the separation of the supraorbital ridges from the forehead by a distinct and broad furrow. In *Pithecanthropus* these ridges continue within the frontal squama, as is also true of the skulls within the whole Neanderthal group.

The entire discussion of the degree of primitiveness, however, is of secondary nature. When compared with other fossil hominids, there is no doubt that *Pithecanthropus* and *Sinanthropus* represent the same general stage of evolution as affirmed by M. Boule, who recently combined the two types under the common name "préhominiens". The differences existing between the two types must be considered as regional or racial deviations. Neanderthal man, as well as recent man, as a rule displays in details a great number of primitive and progressive features existing side-by-side, regardless of the general classification of the types within the order of hominids. Hence, *Sinanthropus* may have retained a primitive character in one of the structures and, perhaps, *Pithecanthropus* in another.

The new discovery of the mandible points exactly in the same direction. Since both the jaw and teeth are rather strongly developed, I doubt whether they actually belong to individuals characterized by such small skulls as the *Pithecanthropus* skulls, although the restorer of the entire head took such a condition for granted, judging by the photograph in the *Illustrated London News*. In the case of *Sinanthropus*, the small skulls (female) have small jaws with relatively small teeth. The mandible fragment, judged by size only, would rather fit the large skulls of *Homo soloensis*. In any event, the teeth are interesting because of the extensive combination of primitive and more advanced characters. The increasing size from M_1 to M_3 is a primitive feature, whereas the shape and patterns of the second premolar and the first and second molars suggest a much more advanced type when compared with the *Sinanthropus* teeth. All the peculiarities specific to primitive *Sinanthropus* teeth are absent in these *Pithecanthropus* teeth (compare my publication on the *Sinanthropus* dentition[3]). Therefore, should the mandible really belong to *Pithecanthropus*, then the degree of primitiveness would once more be directed towards *Sinanthropus*.

The *Pithecanthropus* problem, however, cannot be discussed without referring to *Homo soloensis*. In the publication quoted above[1] I have directed attention to the fact that *Homo soloensis* bears so close a resemblance to *Pithecanthropus* that a conception is suggested that the former represents a male and the latter a female individual of one and the same type. The recovery of the new skull exhibiting the same shape and size as the first one supports this idea. I know that geological conditions seem to contradict such a combination, but as a matter of fact, the similarity is so striking that *Homo soloensis* must at least be considered the next further advanced phase of *Pithecanthropus*. In this connexion, it must be borne in mind that within the *Sinanthropus* group there are small and large skulls with their cranial capacities varying from 850 c.c. to 1,220 c.c. and with corresponding differences in shape and features. At any rate, further discoveries will certainly contribute towards a better understanding of the existing relations.

Thus we proceed to another question raised in von Koenigswald's article. Koenigswald considers the baby skull of Java, the so-called *Homo modjokertensis*, though with certain reservation, as an infantile *Pithecanthropus* skull. Sir Arthur Keith agrees with von Koenigswald on this point. Again, I doubt the correctness of such an interpretation. Since the skull belongs to a very young child, it is difficult to judge it on the basis of criteria valid for adult skulls. This is especially true of the relation between height and length. We know that in young individuals, even in anthropoids, the forehead is much more erect and hence the relative height of the brain case much higher than in adult skulls. However, there are two facts, which, in my opinion, are incompatible with the assumption of a direct general relation between that baby skull and *Pithecanthropus*, so far as the latter is represented by the two adult skulls. One fact is the circumstance that the length of the sagittal border of the parietal bone of the baby skull considerably exceeds the corresponding length of the frontal bone. Such a feature is rather characteristic of recent man, whereas in fossil man and in the great apes exactly the reverse is true. Although that difference is less in very young than in adult skulls, it nevertheless exists. But in the baby skull of Java the length of the parietal bone is, without question, already considerably greater than the respective measurements of the adult *Pithecanthropus* skulls and the *Sinanthropus* skull taken for comparison above.

One other fact must be added. The occipital bone of the baby skull is rather equally curved in the inion region, whereas the adult *Pithecanthropus* and *Sinanthropus* skulls exhibit a distinct angle at this region between the upper and lower portion of the occipital squama. Although this feature may be found to be somewhat altered in young individuals also, it is important that a fragment of a *Sinanthropus* at our disposal which, according to its entire appearance, cannot be much older than the baby skull, shows that characteristic inion angle to be well pronounced already. For these two reasons, I am inclined to consider both of the peculiarities just described as an indication that the baby skull of Java represents a more advanced type than the two adult *Pithecanthropus* skulls, and must thus be attributed as belonging to a *Homo soloensis* type rather than to the latter.

The recent important discoveries of Java have solved one problem, but, as is common in such cases, they have at the same time raised new questions.

Science in India*

KALA-AZAR AND MALARIA

The conquest of kala-azar and certain observations on the chemotherapy of malaria were discussed in Sir U. Brahmachari's presidential address to the Section of Medical Research. The earliest epidemic of kala-azar in Bengal ('Burdwan fever') occurred in the seventies of the last century, when it was probably complicated with malaria. In this epidemic, the fell disease defied every human effort. In more recent times, the epidemic of the disease in the Nowgong district of Assam produced such an appalling mortality that there was a decrease of 31·5 per cent in population of the place in the decade 1891–1900. The mortality from the disease has now been reduced from 90 per cent or more to 1–2 per cent. Including complicated cases, it has been reduced from 99 to less than 10 per cent.

The conquest of kala-azar may be said to have begun when Cristina and Caronia obtained remarkable results in infantile kala-azar of the Mediterranean basin by the use of tartar emetic. It has been observed (Brahmachari and co-worker) that when metallic antimony is injected intravenously in a leishmania-infected experimental animal in a state of fine subdivision, the particles are picked up by the same cells in the spleen as those that harbour the parasites of kala-azar, and that the ensuing struggle results in the complete destruction of the parasites in the speediest way. It is one of the most powerful leishmanocides.

It has been found that, in the campaign against kala-azar, treatment with tartar emetic or sodium antimonyl tartrate had the disadvantage of being long and tedious. In Assam, which was once the hot-bed of the disease, mass treatment with these drugs was therefore found difficult to enforce, as patients discontinued treatment altogether or attended very irregularly after a few injections. It was felt that the difficulties in reducing the number of 'stopped treatment' cases would be overcome more effectively if some drug could be introduced which would be more efficacious than tartar emetic and take a much shorter time to effect a cure. Such a drug was found in 'urea stibamine'. Its value in the campaign against kala-azar in Assam is demonstrated from statistics in the Annual Public Health Reports of the Government of Assam.

* Continued from p. 340.

The figures for the Cachar district are very interesting. Out of 5,188 cases treated between 1925 and 1936, the number of deaths was 56, showing a percentage of less than 1·08. Out of 574 cases treated in 1936, the number of deaths was 2, showing a percentage of less than 0·3. The incidence of the disease in Assam has been reduced from 60,940 in 1925 to 10,587 in 1936, and the mortality from 6,365 to 753 during the same period. The disease has lost all its terrors in the Province, and people who suffer from it are less afraid than those who suffer from malaria.

The Kala-azar Commission, India, used, throughout the seven years of its existence, urea stibamine only, in the routine treatment of kala-azar. According to it, the acute fulminating type characteristic of the peak period of an epidemic responded to treatment with urea stibamine extraordinarily promptly and with an almost dramatic cessation of fever, diminution in size of the spleen and return to normal condition of health.

In 1933, the Director of Public Health, Assam, noted that "It is no exaggeration to say that approximately 3·25 lacs of valuable lives have been saved to the Province". In 1922, in studying the treatment of kala-azar, Sir U. Brahmachari observed certain remarkable skin eruptions caused by *Leishmania donovani* developing in kala-azar patients two or three years after completion of antimonial treatment and apparent cure, though, under ordinary conditions, in kala-azar the skin shows very little involvement or none (dermal leishmanoid). Viable leishmania have been cultured from these skin lesions in test-tubes and sandflies. They are therefore a source of infection, and the conquest of kala-azar cannot be regarded as complete unless these lesions are either averted or quickly cured. In the campaign against kala-azar and its conquest, proper handling of cases of dermal leishmanoid is an important point to be taken into consideration.

Research in malaria therapy has been intense in recent times. In certain parts of India it is of greater interest than kala-azar. The chemotherapy of quinoline and acridine compounds in malaria may one day play an important part in the campaign against the disease and its conquest. While some quinoline and acridine compounds have marked destructive action on paramecia, most of them have been observed to have no action on the parasites of malaria when used clinically in patients suffering from the disease.

Recently a compound having a similar composition to that of quinacrine or atebrin has been synthesized in Sir U. Brahmachari's laboratory. It has been used in the form of the hydrochloride or hydrobromide. Its action in benign tertian and malignant tertian infections in man is identical with that of atebrin. Shortt and Menon have observed that in a series of experiments carried out with this compound and atebrin on monkeys infected with *Plasmodium knowlesi*, the effect of the two drugs in sterilizing the peripheral blood, the cure rate, and relapse rate were identical.

The discoveries of effective anti-malarials and leishmanocides rank among the highest triumphs of synthetic chemistry in its application to tropical medicine.

Sir U. Brahmachari concluded by saying that if along with the conquest of malaria and kala-azar there is in India "a proper balance between labour-saving devices and industry-increasing discoveries", and if her people "will but decide to put in play the methods", which science to-day has provided for sufficient supply of food and clothing and shelter, then the health and economic problems of India, with her endless natural resources, will be solved to a great extent and much of her unrest and unemployment will cease, and she will have the opportunity of being richer, happier, healthier and freer than ever before.

PHYSIOLOGY OF THE INDIVIDUAL IN THE TROPICS

Bt.-Colonel R. N. Chopra discussed the physiology of the individual in the tropics in his presidential address to the Section of Physiology. With the development of bacteriology and immunology, medical science has been dominated by the conception of specific infection, and emphasis has been laid more on the invading organism than on the invaded patient. In modern physiology, also, a good deal of stress is laid on the cellular organization of living bodies and on isolated organs or tissues rather than on the organism as a whole. Man is an organic unity in relation to his surroundings, and therefore his normal physiological processes are likely to be modified by the environmental forces which are constantly impinging upon him. Like all other living organisms, he is endowed with powers of adaptation, and he reacts to his environment in such a way as to produce within himself ideal conditions for life within that environment.

The most important environmental factor affecting the dweller in the tropics is the high atmospheric temperature, associated usually with bright sunlight and excessive humidity. These three combine to make the primary demand on the body—that of heat regulation. There is evidence that acclimatization for generations to a hot climate has endowed the skin of the tropical races with the power of getting rid of excessive heat. The pigmented skin prevents the penetration of heat to the more sensitive tissues, and, by absorbing heat, allows stimulation of local heat receptors and consequent reflex sweating and evaporation. The sweat glands also appear to develop a special adjustment; the sweat is not only more abundant but also contains less chloride than that of the European, an indication that the body is striving to prevent an otherwise serious depletion.

Like the skin, the gastro-intestinal tract also shows some adaptive response. The cutaneous vasodilatation leads to splanchnic vasoconstriction, with diminution in gastric and biliary secretions, and possibly also gastro-intestinal atony, with their sequelæ of loss of appetite and constipation.

The respiratory and cardio-vascular systems also share in the process of adaptation; but it is doubtful whether any permanent change is brought about. Changes in water metabolism undoubtedly occur, with reflected alterations in the state of the body fluids, but the changes reported are not significant enough to deserve special attention. Examination of the blood shows that, contrary to the general belief, a tropical climate does not produce anæmia, but may actually have a stimulating influence on the hæmopoietic system.

There is no unanimity of opinion on the degree to which the nervous system is affected, and experimental difficulties make decision difficult. It seems certain, however, that, so far as the endocrine system is concerned, hot climate reduces the activity of the thyroid-adrenal apparatus. The expected lowering of the basal metabolic rate is, however, not observed.

The natural diet of the tropical native appears to be very well adapted to his environment. The low protein intake tends to keep heat production at a low level, fat is undesirable on account of its high calorific value, while carbohydrate, of which there is abundance, is, on account of its water binding power, ideally suited to promote loss of heat by evaporation.

It is clear that human individuals, like other organisms, receive modifying impressions from their physical environment. It is only natural that, in the process of adjustment, individuals residing in the tropics will develop physiological, biochemical, and possibly pathological states, which will be peculiar to the climatic type and different from others residing in other climatic zones. Unless these peculiar characteristics of tropical climate are known, no definition of a 'normal' individual will be possible. The determination of physiological 'normals' provides the essential base line for the study of disease, and therefore both physiologists and medical men should study the problems of environmental adaptation more intensively than they have so far done.

AMBIVALENCE

In his presidential address before the Section of Psychology, Dr. G. Bose discussed "Ambivalence". It is well known that negativistic states occur both in normal and abnormal persons, and in some cases of dementia præcox the state may attain pathological proportions, but there is no generally recognized satisfactory explanation of the symptoms. Some would postulate an innate characteristic, prompting to contradictory emotional attitudes towards the same object, to which the word ambivalence is given; others tend to limit this attitude to the love-hate situation. Now although opposite types of behaviour in different circumstances and at different times are quite common among normal poeple, no one has sought to explain them by the theory of ambivalence. Strictly speaking, the ambivalency theory should be limited to cases where opposite tendencies are observed to be working simultaneously and so affecting behaviour, but because of the unconscious element ambivalence is never a matter of direct observation, and must therefore be regarded as an explanatory concept.

If it be assumed that the motive force of behaviour is *wish*, then it is easy to see that behind the emotional states of love and hate are wishes of opposite types; the real opposition therefore between love and hate lies in the contents of the corresponding wish situation. Only in the domain of a dynamic entity does the concept of opposition hold good, so that if we are to recognize an opposition between such elements as pleasure and pain, love and hate, subject and object, we must suppose that these entities are of the dynamic order. Pleasure and pain are opposites because they are usually associated with opposite types of reaction; otherwise they are just like any two different experiences, for example, red and green colours.

Still, neither the antithesis between love and hate, nor that between activity and passivity gives us any clue to the solution of ambivalence.

We might make the assumption that pairs of active and passive wishes of all sorts exist in the psyche. Ordinarily the wishes inhibit each other and the ego remains in a neutral state free from apparent strain. Sometimes in the presence of an object the equilibrium of the ego is disturbed and the wish corresponding to the objective situation is thrown out by the ego as a pseudopodium—to use a biological term. The subjective counterpart of the wish is felt by the ego as a striving towards the object. When the act is completed, the *subjective* striving finds satisfaction in the situation of the main ego and the *objective* striving in the situation of the object carried there.

Opposite pairs of wishes may, therefore, be supposed to exist in all wish situations. It is only where reciprocity is possible that the components of the pair become manifest. If there is a one-sided influence in childhood favouring one of the pair of opposite wishes, repression results. Repressed masochism makes sadism ambivalent and vice versa.

It is, then, better to consider ambivalence not as a fundamental trait of mental life, but to assume that pairs of opposite wishes are fundamental. The components of such pairs of wishes may have alternate complete satisfaction in reciprocal acts, and partial satisfaction with unpleasant emotion tones in retaliatory acts. They may not necessarily produce ambivalent states and even when they do, in many cases, the ambivalence is removable, thus showing that it is a repression product.

PHYSIOGRAPHY OF RAJPUTANA

Dr. A. M. Heron's address to the newly instituted Section of Geography and Geodesy on "The Physiography of Rajputana" summarized the results of his geological work extending over twenty years in that area.

Rajputana, covering 130,642 sq. miles, is roughly rhomb-shaped with E–W and N–S diagonals, of about 540 and 510 miles in length respectively. The Aravalli mountains intersect the area running N.E.–S.W., from Delhi to Gujarat, a distance of 430 miles. These mountains are a true folded range, deeply eroded at the present time, and are probably the oldest mountains in the world still remaining as a range. It is to the physical and geological features of the Aravalli hills that Dr. Heron pays particular attention.

After a brief mention of the Precambrian succession which forms the principal geological interest, Dr. Heron compares the present-day features of the two divisions into which the region is divided by the range. To the north-west the country is largely desert and, with the exception of the catchment basin of the Luni river, an area of enclosed drainage in which salt lakes have formed. The origin of the salt and the sand of the dunes of the *seif*, *barchan* and ordinary types is traced to the Rann of Kachh. The solid geology has little effect on the topography. South-eastern Rajputana is morphologically more varied, while desert conditions are replaced by a fairly well watered and comparatively fertile land. The relations between the geology and topography are discussed in some detail.

Dr. Heron then proceeds to his description of the Aravalli range. After pointing out that, in contradistinction to the rest of India, the folding continued to a geologically much later date since the Vindhyan rocks have been affected, he proceeds to show that the Aravalli range was in existence forming a barrier between the two areas (west and east) in which the Vindhyans were laid down. The uplift is considered to be pre-Vindhyan in age.

Referring to the folding of the range and the rocks which were involved, Dr. Heron directed attention to the fact that, in spite of its name, the Aravalli range is composed mainly of rocks of the Delhi System. This system lying unconformably on the Aravalli System is developed in a geosyncline with the softer Aravalli rocks exposed on the flanks. The higher grade of metamorphism and the greater amount of igneous intrusion in the Delhis is attributed to the deeper infolding in the synclinorium and the consequent greater temperature and pressure. The synclinorium is compared to a double fan. Where the handles meet, the folding is believed to be that of a simple syncline, spreading out at either end by the appearance of further folds, by the thickening of some of the formations and by deeper folding bringing higher beds into the core. Details of folding and faulting along the range are given.

Dr. Heron then proceeded to discuss the Mesozoic rejuvenation of the Aravalli range, which was accompanied by the formation of the Great Boundary fault and the disturbance of the Vindhyan rocks. On the evidence given he arrives at the important conclusions that the range was peneplaned during the Mesozoic, at some period not much earlier than the Cretaceous, and was re-elevated before the beginning of the Tertiary.

Evidence was brought forward to suggest the existence of a second peneplane of Tertiary age, while a third of Pleistocene age, the 'Bhangar' or older alluvium, is also present.

Medicine and Eugenics

IN the Galton Lecture delivered before the Eugenics Society on February 16, Prof. John A. Ryle, regius professor of physic in the University of Cambridge, pointed out that the aims of the science of medicine and the science of eugenics are in many respects identical. Medicine, however, in the past has paid too little attention to inheritance, and eugenics too little attention to environment. The neglect of eugenics by the medical profession is shown by the fact that out of approximately 650 members of the Eugenics Society only one fifth are medical men.

Prof. Ryle urged that fuller consideration than at present should be given to genetics in the medical curriculum from the first year of biological study and continued until the final clinical year. He suggested that a study of animal genetics should be substituted for some of the routine morphological study in zoology, and that reproduction, genetics, growth and nutrition should take the place of the more specialized biochemistry and biophysics.

It is, moreover, important that the family doctor should be able to give advice on such subjects as sterilization of the unfit and taxation relief for the encouragement of healthy parenthood, and should be familiar with the significance of population fluctuations, the various causes of decline in physical standards, the origin of mental defect, and so forth. It is owing to the medical profession being insufficiently instructed that members of the lay public have to content themselves so frequently with quacks, doubtful literature and advertisements. Prof. Ryle maintains that it is the function of the medical profession to advise politicians in the matter of planning for a health campaign. In addition to nutritional reforms, housing improvements and other comparable measures within the purview of State medicine, statesmen, communities and individuals alike should devote their attention to the study of pedigrees and encourage an optimum fertilization rate. Owing to the present lack of co-ordination within the medical profession and reliance on local enthusiasm and sporadic individual efforts, progress is necessarily slow. What is wanted is a drastic reorganization on a large scale such as is being carried out in the U.S.S.R.

In conclusion, Prof. Ryle made the following recommendations: First, a national council of medicine, eugenics and sociology should be formed not only to direct education and research in human genetics and social reorganization, but also to transmit to the legislative councils accumulated information with suggestions for reform. Secondly, more stress should be laid in the medical curriculum upon all preventive aspects, especially the preservation of health by nutritional and other social reforms and the application of human and animal genetics to eugenic education. Thirdly, existing organizations, eugenic and sociological, should be employed to interest the medical profession in the preventive and educational role which they should play by instruction in domestic eugenics. Fourthly, a limited number of chairs or readerships should be founded in human genetics, the study of which should be carried on in close association with animal genetics and the biological sciences on one hand and the clinical sciences on the other.

University Events

ADELAIDE.—Dr. James Davidson, head of the Department of Entomology at the Waite Agricultural Research Institute of the University, has been appointed to the Waite professorship of entomology.

CAMBRIDGE.—R. H. Angus, of Sidney Sussex College, has been appointed University lecturer in engineering.

Prof. A. R. Radcliffe-Brown, of Trinity College, professor of social anthropology in the University of Oxford, has been appointed to the Frazer lectureship in social anthropology for the academic year 1938–39.

H. E. Hinton, of King's College, has been appointed junior curator of the Museum of Zoology.

The Raymond Horton-Smith Prize for 1936–37 is awarded to Dr. H. L. H. H. Green, of Sidney Sussex College, for a thesis entitled "Monotreme Teeth: a Study in Mammalian Tooth Development".

The Appointments Committee of the Faculty of Archæology and Anthropology expects to proceed shortly to the appointment of a University lecturer in anthropology. In making the appointment preference may be given to candidates having experience of Oceania and the Pacific area and a knowledge of their peoples. Further particulars may be obtained from Mr. M. C. Burkitt, secretary of the Appointments Committee of the Faculty, Museum of Archæology and of Ethnology, Cambridge, on or before May 28.

EDINBURGH.—The Cameron Prize for 1938 has been awarded to Dr. Karl Landsteiner, member of the Rockefeller Institute for Medical Research, New York, in recognition of his researches on isohæmagglutinins and blood-groups and the influence of his discoveries on the practice of therapeutic blood transfusion.

Science News a Century Ago

Druidical Temples

AT a meeting of the Royal Irish Academy on February 26, 1838, reported in the *Gentleman's Magazine* of the following June, Mr. Petrie gave an account of a very remarkable collection of stone circles, cairns, etc., situated in the town of Carrowmore, in the parish of Filmacowen, and about two miles from the town of Sligo. They were of the class popularly called druidical temples, and had in every instance, one or more cromlechs or kistvaen within them. Many of these monuments were greatly dilapidated, but there were still existing vestiges of about sixty circles with cromlechs, and it was known that a vast number had been totally destroyed by the peasantry. They were all formed of granite boulders except the covering of stones and another of the cromlechs in the great cairn, which were of forms. In all the circles which had been either wholly or in part destroyed human bones and their urns, etc., had been invariably found, and one circular enclosure, outside the group, and of far greater extent than any of the others, but evidently of contemporaneous construction, was filled with bones of men and animals. Mr. Petrie stated that this was the largest collection of monuments of the kind in the British Isles and probably, with the exception of the monuments at Carnac in Brittany, the most remarkable in the world.

The Frozen Soil of Siberia

AT a meeting of the Royal Geographical Society held on February 26, 1838, a paper by Prof. Karl Ernst Baer (1792–1876) entitled "On the Frozen Soil of Siberia" was communicated by Vice-Admiral von Krusenstern. It had long been ascertained, said Baer, that over a great extent of the country, the soil in Siberia was never entirely free from ice. During the summer, the surface of the ground was to a greater or less depth, thawed, but at some distance from the surface a bottom of perpetual ice was met with. Gmelin, the elder, had stated that shortly after the founding of the town of Yakuzk (in lat. 62½° N., long. 130° E. nearly) the soil was found to be frozen to a depth of ninety-one feet and the sinking of a well had to be abandoned. Within the last few years, however, a merchant having attempted to sink a well in that town, was persuaded by Admiral Wrangel to continue his operations until he had penetrated the whole stratum of ice. This he did, keeping a journal of his work. The pit was sunk to a depth of 382 feet, when loose soil was encountered, the temperature of the earth being ½° Réaumur. The temperature at various depths was as follows :

−5	at	77	ft.	−1½	at	305	ft.
−4	,,	119	,,	− ½	,,	350	,,
−2	,,	217	,,	½	,,	382	,,

This immense thickness of ground ice would prove that Siberia must have been for a long period in the physical condition as it was at present. In the actual state of our information it was impossible to determine how widely the layer of ground ice was spread under the surface of Siberia. In concluding his paper, Baer said it would be interesting if the Geographical Society would collect information respecting the extent of the layer of ground ice in North America.

Faraday's Experiments on Conduction

ON February 26, 1838, Faraday recorded in his Diary :

> "Made some expts. with 6 of Daniells' cells on conducting power conferred on water by acids, salts, etc. Found them very different and for a first approximation may arrange them into three classes.
>
> *Sulphuric*, *Nitric*, *Oxalic* and *Phosphoric* acids gives much power.
>
> *Tartaric* and *Citric* acids ; *Potassa, Soda*—*Carbonates* of *potassa, Soda* and *ammonia*—*Sulphate of soda*—*Nitre* and *Bicarb. soda*—give less.
>
> *Acetic* and *Boracic* acids—*Ammonia*—*Corr. Sublimate*—*Percyanide* of *Mercury*—*Iodine*—*Gum* and Sugar—give no sensible power tested by Volta meter but would probably by the Galvanometer.
>
> The results are useful general approximations."

Early Proposals for Steam Navigation

ON February 26, 1838, Prof. Stephen Peter Rigaud (1774–1839), the Savilian professor of astronomy, gave an "Account of some Early Proposals for Steam Navigation" to the Ashmolean Society. The latter part of the paper was taken up by a notice of the claim made that Blasco de Garay in 1543 at Barcelona made the first known experiment of propelling a vessel by the agency of steam. The claim was made in a book published in 1831, entitled "A Year in Spain by a Young American", the author being Capt. Slidell, U.S.N. Another notice had appeared in the *Literary Gazette* for 1827. "The critical examination of the question," said Rigaud, "must be left to those who have the advantage of being acquainted with the Spanish language, and have the opportunity of examining the original authorities, on which the statement depends. The Catalonians, indeed, were always the most enterprising people of the Peninsula ; but the machinery, necessary for the effect here described, seems to be beyond the age in which it is said to have been constructed, and it is difficult to persuade ourself implicitly of its existence".

The documents relating to the incident preserved at Simancas, near Valladolid, Spain, were examined in September 1857 by John Macgregor, who in a paper to the Royal Society of Arts, on April 14, 1858, stated that neither of the letters "contained any mention whatever of the use of steam".

The Royal Gardens

THE *Athenæum* of March 3, 1838, said : "Curiosity having been excited by a statement in the newspapers that the condition of the Royal Gardens has been the subject of an official inquiry, we have taken some pains to ascertain the truth of the report, and we find the facts to be as follows : A Committee has been appointed by the Lords of the Treasury to investigate certain matters connected with the Queen's Gardens at Windsor, Hampton Court, Kew, Kensington and Buckingham Palace ; and under the direction of the Committee, Professor Lindley has been lately engaged in a minute horticultural inquiry into the administration of these establishments. In this duty Dr. Lindley has associated with himself two gardeners of great experience, namely, Mr. Paxton, gardener to the Duke of Devonshire, and Mr. Wilson, gardener to the Earl of Surrey. We have reason to believe that a report has already been made, but as it relates to matters connected with her Majesty's household, we do not feel at liberty to make public the results of the inquiry."

Societies and Academies

Paris

Academy of Sciences, January 4 (*C.R.*, 206, 1–80).

Alfred Lacroix : The Archives of the Academy of Sciences and the biographical index of its members and correspondants from 1666 to 1937.

Marcel Delépine and Alain Horeau : The dimer of crotaldehyde. The hydrogenation of the corresponding acid and the transposition of its double bond by the nickel.

Charles Eugène Guye. The possibility of verifying experimentally the relation $\nu = \nu_0\sqrt{1 - \beta^2}$ of limited relativity.

Paul Gillis : The multiple integrals of the calculus of variations.

Alfred Liénard : A particular case of the problem of Dirichlet for a circular ring.

Marcel Brelot : Some properties of sub-harmonic functions and of *balayage*.

Lucien Malavard : Electrical analogy as an auxiliary method of photo-elasticity.

Douchan Avsec : Vortices in transversal bands in a layer of air heated from below.

Louis Goldstein : The theory of nuclear reactions.

Mme. Marie Antoinette Tonnelat-Baudot : The different forms of a function of action expressed with the aid of complex variables.

Pierre Vernotte : Concerning a verification of Rayleigh's criterion.

Louis Néel : The interpretation of the paramagnetic Curie point of the elements of the rare earth group.

Marcel Rouault : The structure of the $GeBr_4$ molecule. By the electron diffraction method, results have been obtained which agree with a tetrahedral structure for the molecule of germanium tetrabromide. The atomic distances found are Ge-Br, 2·32 A. and Br-Br, 3·79 A.

Jean Cayrel : The Devaux reaction (copper, copper sulphide) on a limited surface.

Alexandre Travers and Hamid Zahabi : Some properties of the hexahydrate of tricalcium aluminate and anhydrous tricalcium aluminate.

Jean Kraft : The uranyl ortho-arsenates.

Raymond Calas : The preparation of two stereoisomeric ($d + 1$) dihydrocamphorones.

Paul Gaubert : The formation and orientation of soft macled crystals in anisotropic liquid drops of *p*-axoxyanisol.

Mlles. Wilfried Heller and Germaine Quimfe : The two possible orientations of colloidal goethite in the magnetic field.

Mengli Enikeff : Researches on the soils of the interior delta of the Niger.

Louis Dubertret and Henri Vautrin : The existence of the lacustrine Pontian in Syria and on its tectonic signification.

Antonin Tronchet : The direct mechanical stimulation of the papillary cells of the tendrils of *Eccremocarpus scaber*.

Albert Vandel : The existence of relations between the arrangement of the chromatophores and that of the muscular insertions in Isopods of the genus *Trichoniscus*.

Theodore Kofman : Morphological reactions in the serum of the cancerized rabbit.

Jean Cuillé and Paul Louis Chelle : The *Tremblante du mouton* is inoculable.

Amsterdam

Royal Academy (*Proc.*, 40, No. 10 ; 1937).

H. A. Kramers : The use of charge-conjugated wave-functions in the hole theory of the electron.

J. Clay : Ionization and conductivity in gases at high pressures. Measurements of ionization in air, nitrogen, helium, neon, argon, krypton and xenon with cosmic rays and gamma rays.

J. G. van der Corput : Weyl's method in the theory of numbers (3) : Two, three or four primes.

R. Weitzenböck : Trivectors (3).

P. E. Verkade and J. van der Lee : Syntheses of glycero-phosphatidic acids and glycero-phosphatides.

E. Dubois : The osterone arrangement of the thigh-bone compacta of man identical with that first found in *Pithecanthropus*.

C. S. Meyer : Some further integral representations of products of Whittaker functions.

F. Florschütz and I. M. van der Vlerk : Fossil cell structure in Early Pleistocene deposits in the East Netherlands.

G. H. R. von Koenigswald : A lower jaw fragment of *Pithecanthropus* from the Trinil layers of central Java.

Jean K. Weston : Notes on the telencephalon of *Mormyrus* and *Gnathonemus*.

Brussels

Royal Academy (*Bull. Classe Sci.*, No. 11, 1937).

L. Godeaux : An algebraic surface of divisor two deduced from the surface of Veronese.

P. Gérard and R. Cordier . Existence of glandular cells in the kidney of the *Aglossa*.

E. Lahaye : Solution of Stórmer's equations by real convergent integral iterations.

C. Surquin : Bernoulli's law in two variables.

O. Rozet : Cyclic involutions of order nine belonging to an algebraic surface.

L. J. Tison : Wear round bridge piers in a river.

A. Grosjean : Some observations on the northern border of the Liége coal-field.

Z. M. Bacq and A. Oury : Note on the distribution of choline esterase in living beings.

Rome

National Academy of the Lincei (*Atti*, 25, 413–524 ; 1937).

L. Petri : Transmission of the leaf-curl virus of the vine through tissues of a resistant variety.

F. Tricomi : Inversion formula of Widder.

L. Cesari : Resolution of systems of linear equations through successive approximations.

G. Pompilj : Cremona transformations of the plane which has a curve of united points.

L. Toscano : Deviation of the permutability in the theory of linear operators.

M. Villa : Varieties in four dimensions which possess ∞^7 conics which are quasi-asymptotics $\gamma_{1,8}$.

G. Colonnetti : Elastic equilibrium of systems in which non-elastic deformations also occur (2).

G. Lampariello : Kinetic interaction between vortices and irrotational currents.

M. Lombardini : Gradient wind.

C. Possio : Rotational motion of gases.

G. L. Andrissi : Variation of the latitude of the Royal Astronomical Observatory on the Capitol from 1920 to 1934 (2).

S. Franchetti: Calculation of the penetration of electrons of some million volts (1).

G. Racah: Isotropic tensors which show particular symmetries (1).

P. Guareschi: (1) Considerations regarding the rapid and approximate calculation of the specific heats of liquids. (2) Association coefficients and their variations as a function of temperature.

A. Banchetti: Reformatsky's reaction carried out on benzamide.

G. B. Bonino and R. Mansoni-Ansidei: (1) Lines attributed to a possible pyrrolenine form in the Raman spectrum of pyrrole. (2) Raman spectrum of *N*-deuteropyrrole.

A. Iandelli and E. Botti: Crystal structure of compounds of the rare earths with metalloids of the fifth group. (3) Arsenides and antimonides of lanthanum, cerium and praseodymium.

G. B. Bonino: Molecular symmetry of pyrrole.

L. Cavallaro: Absorption bands in polar substances at very high radio-frequencies (2).

M. Bolli: Researches on amylases.

Vienna

Academy of Sciences, December 16.

Marietta Blau and Hertha Wambacher: Photographic investigation of heavy particles in cosmic rays. A number of proton tracks, having a mean energy of 12×10^6 e.v., have been recorded. These appear to be secondary particles, as there is no directional effect. Thirty-one nuclear disintegrations have also been recorded, and the energy released in each is estimated to be more than 200×10^6 e.v.

J. Stiny: Structure of the Obir mountain and east–west displacements.

F. Seidl: Dielectric constants and electrical conductivities of annealed and dehydrated Rochelle salt.

O. Ampferer: Junction of the east and west Alps at the Rhine valley.

F. Wessely, H. Hirschel, G. Schlögl-Petziwal and F. Prillinger: Constitution of equol.

A. Demmelmair: Variation of cosmic ray intensity on the Hafelekar according to local and sidereal time. No fluctuation with a period of one sidereal day could be established; but there was a period of one solar day. The maximum occurred at midday and the minimum at midnight. There was also a definite yearly period, the maximum being in the winter.

Washington, D.C.

National Academy of Sciences (*Proc.*, 23, 595–637, Dec. 15).

G. H. Parker: (1) Antidromic responses from the melanophore nerves of the catfish *Ameiurus*. (2) Antagonism in neurohumours as seen in the pectoral bands of *Mustelus*. Cuts across the fin of this dogfish produce a pale band which extends practically to the edge of the fin and has straight sides or irregular sides according as the fish are blanching or darkening respectively. This and other effects are believed to be due to the presence, simultaneously, of the dispersing neurohumour intermedin (causing darkening) and a concentrating lipohumour from the nerves (causing blanching).

E. H. Hall: The four transverse magnetic effects in copper: new measurements. Measurements have been made of the Hall, Ettingshausen, Nernst and Righi-Leduc effects, at temperatures ranging from 20° to 90° C. Using the figures for the Hall and Ettingshausen coefficients, values for the other two can be calculated by the author's theory of dual conduction in metals. The results are in fair agreement with the experimental values.

P. S. Epstein: Magnetic energy of supraconductors.

C. Sobutsky, L. F. Andrieth and R. W. Campbell: Acid catalysis in liquid ammonia. (1) Ammonolysis of diethylmalonate. Liquid ammonia reacts directly with many substances, the reaction being similar to hydrolysis and hence known as ammonolysis. As hydrogen ion often catalyses hydrolysis, so ammonium ion is found to catalyse ammonolysis. Diethylmalonate in liquid ammonia gives malonamide, the yield increasing with the concentration of ammonium chloride added. Equivalent concentrations of different ammonium salts were roughly equally effective.

L. Pauling and J. H. Sturdivant: Structure of cyameluric acid, hydromelonic acid and related substances. X-ray analysis leads to the view that these substances contain a trivalent cyameluric nucleus C_6N_7, consisting of a co-planary arrangement of three fused rings, and resembling the cyanuric nucleus C_3N_3.

Richard Goldschmidt: Spontaneous chromatin rearrangements and the theory of the gene. As a result of innumerable repetitions of pair-breeding in pure stocks of *Drosophila* or in simple crosses involving mutants in a rather labile equilibrium, it is concluded that all so-called gene mutations are chromatin rearrangements. The chromosome is the unit, and a definite order within its texture is required for normal development.

J. D. Hardy and E. F. DuBois: Regulation of heat loss from the human body. Two normal men were studied nude in the large respiration chamber of the Russell Sage Institute of Pathology, New York, in environments ranging from 23° C. to 35° C. under basal and other conditions. No seasonal changes were found from experiments in winter, spring and early summer. Among other results, it is found that regulation of heat loss at 30° and higher is by a combination of increased blood flow to the skin and by vaporization, and is more sensitive between 30° and 35° than in any other range of temperature. Vasomotor regulation of heat loss is effective down to about 28·5°; below this point, heat loss becomes progressively greater than that produced, until a chill is experienced. During periods of basal metabolism, heat loss by radiation is a maximum and that by convection a minimum; convection loss only is increased during a chill. During a chill, heat production increased to 100–150 per cent above basal, while heat loss increased only 10–15 per cent.

J. D. Hardy: Physical laws of heat loss from the human body. An examination of heat loss from a metal cylinder of known dimensions in the calorimeter used for human subjects (see preceding paper). The proportion of radiation loss to convection loss at 25–26° C. is about the same for the human body and the metal cylinder. Applying Newton's law of cooling, it is deduced that 78 per cent of the area of the human body is effective in radiating heat in the position used. Between 28° and 23°, heat is transferred through the body tissues by pure conduction. Above this range, thermal conductance begins to increase, due presumably to increase of superficial blood flow.

Forthcoming Events

[*Meeting marked with an asterisk is open to the public.*]

Tuesday, March 1

QUEEN MARY COLLEGE, at 5.30.—Sir John Russell, F.R.S.: "South Russia".*

INSTITUTION OF CIVIL ENGINEERS, at 6.—(Joint Meeting with other bodies). Symposium on "The Essential Road Conditions governing the Safety of Modern Traffic".

Wednesday, March 2

ROYAL SOCIETY OF ARTS, at 8.15.—E. V. Evans: "Coal Carbonisation and its Importance in the Life of the Nation".

Thursday, March 3

ROYAL SOCIETY, at 4.30.—Prof. J. H. Orton, J. W. Jones and G. M. King: "The Male Sexual Stage in Salmon Parr (*Salmo salar juv.*)".

H. Grüneberg: "An Analysis of the 'Pleiotropic' Effects of a New Lethal Mutation in the Rat (*Mus norvegicus*)".

ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. C. C. Ungley: "Some Deficiencies of Nutrition and their Relation to Disease." (Goulstonian Lectures. Succeeding lectures on March 8 and 10.)

Friday, March 4

GEOLOGISTS' ASSOCIATION (in the Architectural Theatre, University College, London), at 7.30.—Annual General Meeting.

P. McIntyre: "Alps and Glaciers" (Presidential Address).

ROYAL INSTITUTION, at 9.—Prof. D. Brunt: "Gliding and Soaring Flight".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

JUNIOR INSPECTOR to the Royal Commission on Ancient Monuments (Wales)—The Secretary, Sanctuary Buildings, 20 Great Smith Street, S.W.1 (March 2)

ASSISTANT LECTURER IN AGRICULTURE in the Herts Institute of Agriculture—The Deputy Clerk of the Herts County Council, 28 Castle Street, Hertford (March 3).

ASSISTANT ARCHÆOLOGIST to the Royal Commission on Ancient and Historical Monuments (Scotland)—The Secretary, 27 York Place, Edinburgh, 1 (March 9)

ASSISTANT INVESTIGATOR (roof control and haulage) to the Safety in Mines Research Board, Establishment Branch, Mines Department, Dean Stanley Street, S.W.1—The Under-Secretary for Mines (March 12).

ELECTRICAL ENGINEER in the Military Academy of Science, Woolwich, S.E 18—The Commandant (March 8).

ASSISTANTS (Grade III, metallurgy), SCIENTIFIC OFFICER, and ASSISTANT (Grade III, aerodynamics) at the Royal Aircraft Establishment, South Farnborough, Hants—The Superintendent (March 12)

The Shifting Focus of Science

THE shifting focus of scientific interest has received scant attention either from historians or from men of science. The temptation always is to study the changing scene in terms of its great figures, to believe, in atomistic fashion, that each problem is born of the personal intellectual interest of the individual man of science ; that it has been brought to the notice of his contemporaries by a pure but inexplicable effort of imagination. While it is true that creative thinking of an individual nature must play its part in the making of science, it is equally obvious that the movement in interest cannot possibly be wholly accounted for, on this basis. The problems of Faraday and Maxwell were beyond the imagination of Newton, and those of the modern period outside the mental scope of all three. This does not mean that Faraday and Maxwell were greater figures than Newton, but rather that no man of science can do other than concern himself with the problems characteristic of his period.

The changing face of science can be seen without difficulty to fall into clearly defined stages. We have just suggested three. Each phase is carried through by the activity of the individual scientific workers, great and small, contributing in various measures, partly driven on by the developing internal logic of the subject and its accumulating experimental knowledge, partly canalized and fed by outside social forces not normally apparent to the individual workers. How scientific work is financed, and for what social purpose that work is pursued, for example, is a question the answer to which, in these days of industrial and governmental research, points to one only of the socially determining factors. The shifting focus of science, however much it may provide subjective satisfaction to its devotees, is nevertheless an objective feature of Nature, and therefore, if for that reason alone, a fit subject for scientific investigation.

To-day we are witnessing just such a shift. It began tentatively in the early days of this century with a scrutiny of the logic of mathematics and a study of the methodology of science. It passed to a series of startling attempts to evaluate the philosophical implications of more recent scientific knowledge, implications that sought to deny the certainty of science and strove to lead it back into mysticism. The significant feature of this phase was that these pronouncements were couched in popularized writings, a concession to a sense of social responsibility. Now at last a serious attempt is being made to probe further back to the social origins and social consequences of scientific discovery. The alertness shown in the columns of NATURE to the social possibilities of science, to its destructive as well as its constructive features, to the travesties of truth that are used to bolster up national doctrines, and generally to the distortion and prostitution of science to ignoble ends, is itself a significant feature of this same analysis. Scientific history, like ordinary history, is at last beginning to be seen in its social context ; and the shifting focus of science is part of its history.

The new concern of men of science with the uses and misuses of science has undoubtedly developed with the increasing tenseness of the international situation. The concern of this journal with these matters evidently derives from this source, but did not in fact become apparent until the latter had reached a critical stage. Nevertheless, the social background was always there for study. It required a social crisis to direct our attention to it.

Every shift in interest of science is accompanied by opposition on the part of those absorbed in the older problems and convinced that the new development leads away from the true path of scientific rectitude. A multitude of specious reasons are certain to be brought forward to show that political prejudice must necessarily intervene to prevent the formation of balanced judgments. Such considerations need not deter those who are genuinely concerned with the trend of scientific development as a feature of natural change.

The personal motives that urge individuals rather than the group to concentrate on such questions when the time is socially ripe for their study are many. In "Mathematics for the Million"*, for example, the author is apparently induced to do so in order to take the mystery out of mathematics, and to open the door to an understanding of its meaning for the ordinary citizen. How mathematics could be anything but a mystery to those who have not perceived its social sources is itself a mystery. In this respect, it is sufficient of a miracle to many scientific workers. To mathematicians who do not see it as one of the forms of social energy, it can have but a restricted meaning. In his own way, Hogben has established beyond dispute the existence of a qualitative relation between the growth of mathematical facts and the severely practical problems of the society that gave them birth. That is in itself a significant scientific advance. What requires further elucidation is the changing nature of this relationship.

In its early history, society encountered quite definite immediate problems that required for their solution a definite mathematical technique. By the eighteenth century, the situation in this respect had become drastically transformed. The new merchant and industrial aristocracy was purchasing social prestige by the endowment of university foundations, and educational institutions generally. While out of the practical needs of social life there had blossomed forth the earlier mathematics that dealt with the directly important problems of mensuration, experimental practice had also been called into being for these same ends: and experimental practice involves theory, and theory its mathematical technique, and mathematical technique its special tools and its specific logical problems. To such questions could the universities devote themselves, but the linkage with the severely practical problems of social life, the problems of the common man, while it still existed, had become more remote. The danger for us lies in the belief that that link no longer exists, a belief that shows itself in the idea that mathematics is an independent logical discipline with an absolute line of cleavage between its pure and its applied form. It shows itself in the effort to accord to mathematical ideas a priority over the physical facts of the world and so to present the universe and the struggling society on this earth as a series of grandiose mathematical theorems. Hogben's book is not a mathematical text-book except in a very popular sense—in itself a very important sense—but if its publication should serve to direct attention to the social linkages between the sciences, it will have performed a very significant service.

The End of the Road

A Comprehensive Treatise on Inorganic and Theoretical Chemistry

By Dr. J. W. Mellor. Vol. 16: Pt. and General Index. Pp. x + 811. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 63*s*. net.

THE road of inorganic chemical knowledge is paved with bricks, of silver and sodium, lithium and lead, platinum and phosphorus, helium and uranium, representing all the elements which Mendeléeff provided for and more besides, as well as their numerous compounds; it is surfaced with what road experts call a binder, but which we, the initiated, designate as 'Mellor's magic', a highly original and individual variety. Slowly the magic has prevailed, as good magic always must when diligently applied, and so at last the end of the road has been reached—index and all. Riders in quest of knowledge can traverse it from end to end: it has been well and truly printed.

In more prosaic language, Mellor's "Comprehensive Treatise" is completed: in fifteen years, the vast field of inorganic chemistry has been surveyed. Such an achievement ought to be a matter of national congratulation and every Britisher should be proud that there exists such a treatise in his own language. His continental scientific colleagues have for some years borne the burden of similar publications in chemistry, thereby ensuring a large amount of cultural propaganda; for this reason alone, it is most pleasing that there is now a work of outstanding excellence which will spread abroad British scientific culture.

That the book is outstanding has already been demonstrated in the previous fifteen volumes; its preparation, even if it has become a matter of routine, has involved a tremendous amount of hard work of an extremely conscientious character, coupled with the ability to seize the essentials and classify the material in a form which makes it easy of access for the reader.

Chemists, and indeed that far wider circle of persons in any way concerned with inorganic substances, now have a timely opportunity to testify to the debt of gratitude they owe to Dr. Mellor. The task he has undertaken, as anyone who has done work of this kind knows, has been not merely an occupation but something much more strenuous amounting to a whole-time job and the sacrifice of leisure; if it had not been a labour of love, its completion would have been indeed impossible. As it is, one can only hope that the sacrifice of fifteen years at an important period of a man's life has carried with it some recompense and reward to the author. The more thoughtful who consult the book to-day and in the years to come will spare perhaps a moment to think gratefully of him; the hasty will omit even this much unless they fail to find the particular information in the detail and form they want, when perhaps they too will realize the magnitude of the task

The day is long since past when any man can know all chemistry or even one branch of it; although sitting as honours students, the examiners do expect us to qualify in regard to the questions they set at random. It should become clear when these sixteen volumes are set out in stately array on the shelf that the function of education is to teach first the fundamentals, then how to find the information, to know how it has been obtained, to be able to criticize it and utilize it to the desired ends. The amount of new work published every year has now to be measured in yards of shelf room occupied instead of in feet, and the resources and organization of the societies engaged in producing abstracts are strained to breaking point. General reading has become largely impossible, a most regrettable feature; specialist reading is helped by monographs and annual reports. One result is that the learned transactions no longer have their former appeal to any considerable number of members of a society, so that while their cost is increasing, the membership grows less. This is not the occasion on which to suggest any remedy for the trouble, which is a world-wide one and has already become acute.

Fortunately for the worker or specialist, whether in academic or industrial practice, there still exists a limited number of people, of whom Dr. Mellor is the outstanding British example, who are not dismayed by the magnitude of the task and are willing to collect information in a form and according to a plan which makes it easy of access. By arrangement according to certain conventions, by the use of black type and other simple devices, it is not difficult to trace the paragraph giving the desired information.

Dr. Mellor has a somewhat unusual mixture of talents. Few of those who form a mental picture of him as the result of their study of the "Inorganic Chemistry" would recognize him as the author of a book entitled "Uncle Joe's Nonsense", in which he displays high ability as a humorist both in text and illustration. The reviewer greatly values a set of menu cards, for which "Uncle Joe" was responsible, from the *Laconia* on the occasion of the visit of the Ceramic Society to America. It may be that these talents have contributed to make the treatise what it is, so much more than a dictionary or compendium, actually readable in parts and definitely original.

It has been so often reviewed that the resources of the literary flower shop have been largely exhausted in throwing bouquets which the author must be satiated to receive.

The late Prof. H. E. Armstrong was one of its admirers; he used to say it helped you to read chemistry, which he regarded as a most important as well as practically a lost attribute of the chemist. He himself attached much importance to critical reading, in which the reader did not merely accept the statements but also developed his intelligence in seeking to understand their implication.

This volume contains the index to all the volumes, 400 pages in double column, prepared by Miss E. M. Rigby, which gives reference both to each individual compound and to more general topics such as catalysts.

The author is loath to write finis, for we are promised two supplementary volumes which will include the developments and discoveries of recent years, particularly those relating to the elements which were treated in the early volumes. In addition, Mellor is unwilling to leave all compounds of carbon to the organic chemist, and therefore proposes a special volume to deal with the borderland compounds of carbon with hydrogen and nitrogen.

E. F. A.

Animals in Ancient Rome

Animals for Show and Pleasure in Ancient Rome By George Jennison. (Publications of the University of Manchester, No. 258.) Pp. xiv + 209 + 8 plates. (Manchester: Manchester University Press, 1937.) 12*s.* 6*d.* net.

THIS is a remarkably interesting book owing to the fact that the author combines the qualifications of being a scholar and an official of the Bellevue Zoological Garden at Manchester. Mr. Jennison's book has an extraordinarily widening influence. No one before—certainly in English—has been at pains to collect from all classical sources the notices of wild animals brought for any purpose to ancient Rome—for the games, for menageries or as private pets. The result is a brilliant justification of taking up a rather out-of-the-way line of research. It is not only illuminating in itself but also sheds light on all the surrounding subjects—the character of the Roman people and of their successive emperors, the trade-routes and the spread of Roman influence in the ancient world, the climatic and other changes in the countries from which the beasts were drawn.

Another special merit of the book should be noted. Being written by a man in professional intimate contact with the wild beasts and birds of which he writes in the ancient world, it is full of interesting touches about their life and habits, which show how little these have changed. The men have changed more than the beasts. Mr. Jennison tells us of the weak spot in lions—the backbone just above the loins ("I have known two lions killed unintentionally by a blow there from a broomstick") and then shows how well this fits in with the description in the poet Statius of the death of a trained lion in the arena. He knows how difficult it is to train stags to go in harness and applies this to the procession of the maiden priestess of Artemis in a car drawn by stags and described by Pausanias in the second century A.D. He knows the difficulty of breeding leopards in captivity and a host of other things which bring into high relief the skill, patience and expense expended in the Roman world for the production of their great beast shows and *venationes*. He is equally well informed on the domestic side of the culture of animals by the ancient Romans, telling us, for example, how much the breed of chicken has improved in modern times, as the ancient hen would only at the best lay her sixty eggs a year.

The absorbing interest of the book, however, is its description in detail of how the animals were used for show and slaughter in the arena. It is on the whole a revolting tale, for though there was much training of the beasts for wonderful tricks (lions that would hold hares in their mouths without biting them, dancing horses, monkeys playing draughts, etc.), yet the predominant motive was the popular passion for the sight of deadly sports. The apologists for the Romans trace back this passion to the Etruscans, who seem to have practised gladiatorial games. But the Romans improved on their masters in this respect as in others, and there was little abatement in the passion until the poverty and the Christianity of the later Empire gradually led to the emptying of the arena.

The games, including the slaughter both of men and animals, was the recognized way in which generals and leading magistrates aimed at popularity. Larger and larger numbers of beasts were collected from the provinces and stranger and stranger creatures sought for, to make each *venatio* more distinguished. Elephants were first introduced in the third century B.C. for the triumph over Pyrrhus and became the 'royal beast', to be owned only by persons of the highest rank. They were, however, used not only for ceremonial and warlike purposes but were also slaughtered in the circus. This was so horrible and pathetic a sight that even the Roman crowd protested. They rose and cursed Pompey, who had provided this delicacy, and Cicero, who always expressed the best feeling of his time, wrote to a friend that there was some sort of kinship between that animal and man. Julius Cæsar brought in the giraffe, but there is no evidence of its slaughter until the time of Commodus—a sign both of the gradual worsening of the popular taste and of the mad-dog character of the man.

Nothing is more striking in the story than the reaction of this popular passion for bloodthirsty games on the minds of the rulers who provided, and were responsible for, them. The worst—Nero, Commodus and Elagabalus—revelled in them and often took part themselves. But none was strong enough to make a stand and reform the whole wasteful and abominable system. Trajan, who as ruler was the ablest and most successful of the line, inaugurated his reign by making a public demonstration of simplicity and economy by entering Rome without a procession, without a chariot, without even a horse. The populace saw a tall powerful upright man pass up the Via Sacra on foot accompanied by his wife and a few personal friends. His well-known rescripts on the right method of treating Christians in the provinces are a model of humanity and good sense. Yet the same man in A.D. 107, celebrating his Dacian triumph, authorized games for 120 days, during which 10,000 gladiators fought and 11,000 animals were done to death. Marcus Aurelius, whose instincts revolted against the shows, actually attended some of the most brutal, though he turned his back when the specially well-trained man-eating lion was performing his feats.

Of all such sensational facts Mr. Jennison gives us enough, but not too much, and his book is, besides, a fascinating storehouse of the natural history of the ancient world. When the first chimpanzee was seen in Greece; were polar bears ever transported to Rome; how the crocodile is the easiest of all wild animals to trap; how long were lions extant, wild, in Europe. The book is a rare model of minute and extensive scholarship combined with practical knowledge, good judgment and clear arrangement. The production also sheds great credit on the Manchester University Press.

F. S. MARVIN.

Nuclear Physics

Structure of Atomic Nuclei and Nuclear Transformations

By G. Gamow. Being a second edition of "Constitution of Atomic Nuclei and Radioactivity". Pp. xii + 270. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 17*s*. 6*d*. net.

IN the preface it is stated that whereas in writing the first edition the author felt unhappy because there were not enough experimental facts and theoretical calculations, he now feels there are perhaps too many. Indeed, nuclear physics has undergone an enormous change since the publication of the first edition, of which in the present edition nothing but the memory is preserved.

At that time the author was one of a few pioneer workers in the field, the number of problems that could be understood was strictly limited, and the book was mainly intended to show the applicability and usefulness of quantum theory in nuclear problems, together with a fuller account of the passage of charged particles into and out of the nucleus, which, thanks to his own work, was then already well understood.

The rapid development which followed the discovery of new experimental facts and new particles, but which owes much to Prof. Gamow's early work, brought innumerable other workers into the field, which has now lost much of the charm of the unexplored and has become rather more a branch of theoretical physics. Although the book is still more concerned with the general ideas than with too detailed applications, it has to deal with work in a wide field, done by different people with different methods and different (usually mutually exclusive) approximations. This makes such a general report a very necessary but at the same time a very difficult task to undertake. We are very fortunate that it was undertaken by a man like Prof. Gamow, of whom we can confidently expect a lively account which will not entangle us in a jungle of mathematical detail but will pick out the main ideas and use simple pictures as much as possible. It is very refreshing to read such passages as the account of work on the "shell structure" of nuclei: ". . . it is not referred to in detail here because the author was never able in studying these articles to remember the beginning when he was reading the end." This is in the best Gamow tradition, and we can only regret that there are too few passages of this kind. On the whole, the author is more serious, more the impersonal and impartial reporter than before.

One of the difficulties that such a reporter has before him is to steer the good middle course between assuming all the mathematical apparatus of quantum theory to be familiar to the reader (which would make the book lose its appeal to experimentalists) and to explain the methods wherever they are applied (which would bring it to about the same size as another recent book in the same series). This is evidently a matter of taste, but to the reviewer's taste one meets rather too frequently expressions such as "Simple considerations show . . .", where a few words would have been sufficient to make clear what the nature of these considerations were, or where a reference to a text-book could have been given. In general, references are treated rather casually; papers are often indicated by "it has been shown that . . ." and even when we are given the name of the author, it is often not said where and when he has shown it. In two cases (pp. 128, 173, 219) the footnotes send unsuspecting students off to the library on a wild-goose chase for non-existing periodicals, and only the initiated will understand the subtle jokes.

It is unfortunate that in one or two instances in which the reader has to take it on the author's authority that something "can be shown", slips have occurred. For example, on p. 54 the "very intense" fields referred to are of the order of 100 gauss; the Dirac wave equation is not the only possible Lorentz invariant equation for a particle

(p. 60); the definition of 'odd' and 'even' terms in the footnote on p. 71 is rather confusing. A mass-spectrograph is not usually employed to measure particle velocities, and an elementary particle of spin ½ is not normally referred to as a "rotator".

A good book takes some time to write and publish, and with the present rapid development of the subject it is unavoidable that some passages should be out of date by the time the book is published. In this case, the book was written immediately before the publication of Bohr's theory, which not only opened the way for solving problems that had before remained unexplained but also made it clear beyond doubt that the one-body picture (motion of one particle in a suitable potential field) is entirely inadequate except for such problems as the passage of a charged particle through the potential barrier surrounding a charged nucleus. Prof. Gamow warns us against the excessive use of this method (pp. 200, 208). Yet in many places the old optimism of this strong adherent of the one-body picture breaks through. An attempt at justifying a moderate use of the picture is made in the preface on the grounds that a more complete treatment would be very complicated if not impossible. But if one has reason to believe that some results are independent of the one-body picture, it ought to be possible to derive them without it; and if one has no such reasons, the validity of a method cannot be established by the argument that there is no better method available.

The new Bohr theory has already led to many new results, and has thus greatly increased the wealth of material which Prof. Gamow deplores in his preface. Let us hope that future development, by deciding which are valid and which invalid approximations, and by elimination of unreliable speculation, will reduce the bulk of papers he will have to read before writing the next edition.

Dr. Feather is to be congratulated on succeeding in putting the book into the chains of "orthography and conventional idiom" without spoiling its freedom of expression and its liveliness. R. P.

Plant Ecology in Education

(1) Plant Ecology

By Hilda Drabble. Pp. 142 + 12 plates. (London: Edward Arnold and Co., 1937.) 7*s.* 6*d.* net.

(2) Ecology in Town and Classroom

By Dr. R. Bracher. Pp. 96 + 3 plates. (Bristol and London: J. W. Arrowsmith, Ltd., 1937.) 2*s.* 6*d.* net.

THE increasing replacement of the older teaching of a somewhat disjointed nature study by a more truly scientific course in ecology in schools and colleges has resulted in the need for text-books to serve both the teacher and the student. The two publications here noticed are very dissimilar in aim and content.

(1) Mrs. Drabble's book carries the subject, for plant ecology of the British Isles, approximately, though with several important exceptions, to the general B.Sc. standard of the University of London. It is a concise and adequate summary of much of the more important research on the synecology of plant communities published within recent years, and as such can be strongly recommended to both teachers and students. The twelve plates, mostly from photographs by Prof. E. J. Salisbury, illustrate relevant facts concerning the composition and history of a wide range of types of vegetation. The forty-five test questions should enable students to estimate their knowledge of the subject in advance of examinations and to familiarize themselves with the, usually very fair, type of questions set for them to answer.

There is some justification for the criticism that such a book 'spoon-feeds' the student too much. It is suggested that, if another edition be called for, more emphasis should be placed on practical work by the students themselves. Plant ecology offers a wide scope for investigations in the field, the experimental garden, and the laboratory, and it is advisable that students should be urged to solve its problems by their own experience. The study of the life-histories of single plant-species (autecology) should also be encouraged, and general suggestions for such research might well have been included, with one or two actual examples.

(2) Dr. Bracher's book is limited in scope. It is complementary to her "Field Studies in Ecology" published, in a similar format and at the same price, in 1934. It deals, in brief outline, with the botany, from an ecological point of view, of streets, waste ground, coal tips, fresh waters and tidal river banks. The teacher in a town school should obtain useful ideas from reading its pages. In many towns, at least in the suburbs, even small houses have gardens, and allotments are not unknown. Some of the rather numerous blank pages might well have been utilized to indicate how much ecology can be learnt in gardening, and indeed, must be learnt if the gardening is to be successful. W. B. T.

Fish who Answer the Telephone:
and other Studies in Experimental Biology. By Prof. Y. Frolov. Translated from the Russian by Stephen Graham. Pp. x+168+14 plates. (London: Kegan Paul and Co., Ltd., 1937.) 6*s*. net.

THIS chatty little volume should be welcomed by experimental biologists and will make fascinating reading for the layman who is at all interested in the experimental work now being prosecuted on animal behaviour.

The work of Pavlov is well known to all biologists—especially physiologists—and Prof. Frolov, who worked with Pavlov, has for many years pursued similar lines of investigation. Though this book (with a misleading main title, since it signifies the content of one chapter only) does not claim to give scientific detail of value to research workers, it makes interesting fireside reading for a biologist and gives him a good insight into the experimental method of Frolov and his school. Furthermore, many biologists, especially those beginning their careers, will learn much of academic interest; for example, that *Amphioxus* was discovered by Alexander Kovalevsky in an inlet on the Crimean shore, that the well-known Marine Biological Station at Naples was first of all suggested by the German biologist, Dohrn, and is actually the oldest of such stations, that Frolov himself was the first to claim to have demonstrated a sense of hearing in fish (though whether Prof. von Frisch would agree is an open question), and that much which has been written about instinct and behaviour in ants is the product more of imagination rather than of observation.

More mature psychologists and physiologists will be pleased to revive their memories of work on the behaviour of dogs, experiments on the behaviour of chickens even before they are hatched, and so forth.

Anyone opening the book will be unlikely to put it down until he has read it from cover to cover. Mr. Graham is to be congratulated on translating the work in a most pleasing style.

Geological Excursion Guide to the Assynt District of Sutherland
By Dr. M. Macgregor and Dr. J. Phemister. Pp. 62+4 plates. (Edinburgh: Edinburgh Geological Society, 1937.) 2*s*.

THANKS to the Edinburgh Geological Society, the visitor to the Assynt district of Sutherland is now well equipped. The authors give a carefully planned descriptive itinerary of a series of seven excursions to ground easily accessible from Inchnadamph. All the localities are capable of being visited and examined during a week's stay in the neighbourhood; shorter itineraries also are provided, indicating how to use to the best advantage periods of four, three and two days. The detailed excursion section of the guide is prefaced by a short but clear summary of the geology and structure.

The thoroughness of the authors is shown by the provision of a glossary of place-names, an index, blank pages for notes, and details regarding transport and accommodation. The details of the excursions have been carefully checked in the field, and are fully illustrated by four excellent colour-printed maps and three other sketch-maps in the text. The visitor may be confidently assured that with this guide in one pocket and the one-inch Geological Survey map of Assynt in another he will miss none of the main features of this fascinating district. He must not forget the map, for it contains important 'vertical' and 'horizontal' sections which make it an essential complement to the guide.

Enthusiasts will find that the excursions keep them fully occupied. Non-specialists, however, may think that the petrological picnics to Loch Borrolan (of borolanite fame) and Loch Ailsh might be replaced, in part at least, by an excursion of a more leisurely character to one of the places they have already visited; for they are sure to have fallen in love with at least one particular spot or view in such wonderful country.

Technical Electricity:
Principles and Practice. By J. E. Phillips and Dr. R. W. B. Stephens. Pp. vii+288. (London: The Technical Press, Ltd., 1937.) 7*s*. 6*d*.

THE great difficulty with students of electrical engineering in technical colleges is that they have very little training in physics, and several well-meaning text-books have been produced recently which try to instil fundamental magnetic and electric principles in the shortest possible time, and without making the student tired with difficult discussions about electro-magnetic units and the reason why one way of deducing our definitions of the intensities of fields and so on is preferable to another. There is always the outstanding difficulty why we use unit magnetic poles for definitions when no such pole exists; it is a difficulty which each teacher must solve for himself, before trying to train the immature mind to think in similar terms. The present authors succeed as well as some others, but perhaps tend to err on the more practical side. This is a good fault, however, since the type of student in view is best appealed to through his practical experience—sometimes more up to date than that of his teacher.

L. E. C. H.

Modern Management
By Prof. J. E. Walters. Pp. xiv+337. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 15*s*. net.

THIS book gives a reasonably comprehensive account of the methods of modern management and of the practical applications of the scientific method to various phases of management. It is emphatically not a book for the general reader; but if it contains rather too much detail for him, those who are concerned with particular problems of management may perhaps regret that its account of the Gantt Chart, the Bedaux system and similar matters is rather too condensed. On the whole, however, it is a well-balanced work, although the section on organization and its principles might with advantage have been expanded. Selected bibliographies are appended to each chapter, and these are reasonably representative, although relating in the main only to American publications.

Soil Erosion: the Growth of the Desert in Africa and Elsewhere*

By Sir Daniel Hall, K.C.B., F.R.S.

USUALLY the soil is regarded as something particularly stable, but this stability is almost wholly due to its normal covering of vegetation. There is always a danger that if the cover of vegetation is removed the soil itself will begin to move under the action of either the wind or the rain. Rarely do we see these actions at work on a large scale in England; the climatic conditions are not favourable, for our rainfall is gentle and evenly distributed throughout the year, and our big winds are mostly associated with rain. It is in semi-arid regions, where long periods of drought may be followed by torrential rains, that soil erosion becomes an active danger.

The earliest cases of erosion to be noticed are those which follow deforestation in regions where the mountains in which the rivers take their rise are below the permanent snow-line. In such countries, typically in the eastern Mediterranean —Calabria, Greece, the greater part of Asia Minor— the natural sequence is forest on the higher slopes where the rainfall is greatest, passing into upland meadows as the slope grows less and finally into river meadows as the river nears the sea. There is no evidence in support of the belief that forests increase the rainfall of a country; but they serve as its regulator. The spongy soil below the trees, rich in humus, absorbs the rain as it falls, whereby it reappears later in the springs and furnishes the watercourses and rivers when the rainy season has passed. But too commonly the forests have been cut down without any regard to their regeneration; not only has the maximum of timber been cut out but there has also been the desire to extend the grazing, and unfortunately in these Mediterranean countries goats are among the chief grazing animals. Hungry goats will eat anything that grows; they destroy every seedling tree as fast as it gets its head up, they complete and extend the destruction the woodcutters have begun. At the same time, with their sharp hooves they break the surface of the soil; in other places they tread hard paths down which the rain begins to run with gathering volume and velocity. In a very short time during the rains, gullies begin to form as the soil is washed downhill; year by year the gullies extend and bite deeper into the earth until in no long time—a generation or two—the hillsides that had been forest and upland meadow get bared down to the hard infertile subsoil or to the rock itself.

Nor does the damage end there; the rainfall running off the bared hill country without a check develops as a torrent lower down, attacking the meadows bordering its course. The earth also that has been washed off the hillsides is carried down to the plains where the rivers lose their velocity; there it is deposited and turns the river into a chain of malarious swamps, chokes its mouth and destroys any harbour that was there. Such has been the history of much of the fairest land on the seaboard of the Levant; on the heights, bare rock where once forest and meadow flourished, rivers that are torrents in winter and dry in summer, old seaports no longer accessible. The destruction of the forest was thus a major factor in the decay of Greece and of Rome itself; it meant in the first place the loss of farming land and of the agricultural population which formed the backbone of the early armies of the republics. With the swamps came the spread of malaria, which again has been invoked as one of the great causes of the fall of ancient civilization.

The most spectacular form of soil erosion is that exhibited by the vast dust-storms which, in 1934 and 1935 especially, swept over the United States east of the Mississippi. A vast area, which included western Oklahoma, western Kansas, eastern Colorado, the Panhandle of Texas and parts of Wyoming, has become known as the Dust Bowl. In 1934 it was estimated that on a single day 300 million tons of rich top soil were swept as far away as the Atlantic. There is a story that in the diary of an old Nebraska doctor was found the entry "June 14th. Hot as hell, wind 40 miles an hour, two Kansas farms go by every minute".

The causes of this terrible wind erosion are easy to discern. It arises only in comparatively arid districts where the rainfall is below the 20-inch level, and (in America in any event) where the fundamental subsoil is of a rather sandy type—a recent glacial drift. Before white settlement, these regions were clothed with grass and were the natural home of the buffalo. Some of the land was good grazing, with a fair depth of black soil rich in humus; in the drier parts the sod was thin and there were only a few inches of soil. The black soil regions were fertile and were the first to be broken up; the poorer land was kept for ranching, healthy for either cattle or sheep if not too closely stocked. The plough, however, began to encroach upon these thin soils, with great rapidity when prices of cereals went soaring up from 1917 onwards. At first all went well, for the cultivation began in a cycle of good rainfall seasons and there was some stock both of humus in the soil and of accumulated rainfall below. Years of drought followed when the original subsoil reserve of water had been used up, and the light soil, no longer bound together either by vegetation or humus, began to drift in the fierce winds that sweep over those great plains. The plough has destroyed the binding power of the soil; the wind is then able to remove the whole of the fertile top layer of soil and leave nothing but the denser subsoil, which is too infertile to carry a crop. Nor has it been the case that the good soil is merely transferred from one farm to the next; as a rule in Canada it has been swept right away into the Great Lakes or the barren lands to the north, or even into the Atlantic itself.

---

* From a Friday evening discourse delivered at the Royal Institution on November 12.

Without doubt, much of the poorest of this land ought never to have been ploughed even in boom times; once the crust has been broken it becomes a sort of running sore always eating into the land on its margin. As a ranch under its natural vegetation it had a modest productive value, and to that use it must return.

In Canada, improved methods of cultivation have been introduced to minimize the danger of soil drifting. Since it is inevitable that at certain seasons of the year the soil should be cultivated while bare of a crop, the practice has been introduced of dividing the land into strips, the bare land alternating with land under crop in place of the former large areas under the same treatment. Thus the incipient soil erosion under the wind is checked before it can proceed far, and a very efficient measure of protection is attained.

One other major work of reconstruction is needed, though it is being taken in hand on a large scale in the United States, and that is the establishment of shelter belts to break up the fierce winds which rage over these open treeless spaces. It is not an easy matter to get trees started, especially the north in Saskatchewan and Alberta, where the range of species that will stand up to the extremes of climate is limited, but a certain number of suitable species have been found. Besides the original planting of cross-country belts, farmers are being taught to protect their own holdings.

Erosion by rain is even more common wherever the cultivated land lies on a slope and the rains are heavy. The danger does not lie in a large annual rainfall; some of the worst destruction is wrought in regions where a low total is concentrated into short intense spells.

As soon as the rate of fall becomes sufficient to cause an actual flow of water at any spot it acquires an excavating power and begins to cut a channel in the loose earth, a gulley which not only enlarges itself by the undercutting of its banks but also tends to eat its way backwards. Gulleying can be initiated either by careless management of cultivated soil or on grassland by overgrazing, which bares the surface. Even before actual overgrazing sets in, both cattle and sheep will tread bare tracks along which streams will begin to flow during the rains and to acquire sufficient velocity to eat into the soil. In however small a way such gulleying starts, if it is not checked it extends itself from season to season, until eventually, by a sort of geometrical progression, the large area may become impassable to man and beast. Though agriculture generally is indicted as the initiator of erosion, more properly it is the recklessness or the want of foresight in man that should be blamed. Erosion is like fire; a trivial accident may start it, and if not checked at once there may be no staying its progress.

In a recent book "Rich Land, Poor Land" is described a great crater in Georgia, 200 feet deep, that had arisen from a simple gully. "Do you know what started him? A trickle of water running off a farmer's barn 40 years ago. Just one dam little trickle, and now a third of the county's gone—forty thousand acres." An area in Tennessee ten miles in diameter has been gullied to desolation through destruction of the vegetation by the fumes of a copper smelter.

The loss of land is not all that the community suffers. The soil that the rain starts moving reaches the rivers and has to find a resting-place somewhere. It is in regions liable to erosion that irrigation becomes of so much importance, and dams are thrown across the rivers to store the flood-water of the rains. But no one had foreseen what masses of sand and silt would begin to choke the reservoirs when erosion was going on at the head waters. The Rio Perco is reported to be pouring every flood season 9,000 acre feet of silt into the lake built to supply New Mexico with its quota of water from the Rio Grande. The last Mississippi flood was the wildest and most dangerous of any in the history of the river, notwithstanding all the protective measures that have been carried out, simply because the lower river is being raised more and more above the level of the surrounding country.

A large amount of work is now being done in the United States to control gulleying and to reclaim the devastated land. In the early stages, gulleying can be checked by throwing dams across the gash, dams which may be timber or concrete or just bushes, alive or dead, anything that will check the rush of water and cause the sediment to begin to accumulate. Even more effective has been the introduction of rapidly growing plants, which not only check the flow of water and filter out the silt but also bind the earth and stop further washing. The Soil Conservation Service in the United States is bringing into play all the resources of science and engineering to repair the damage which had been inflicted upon the land of the United States by hasty exploitation. I would instance again the Civilian Conservation Corps, that inspiration of President Roosevelt's, which in 1932, when the youth of America found no prospect of employment of any kind on leaving school or college, gathered some 300,000 of them for service and set them to work to clean up the countryside. They were turned on to fire-prevention work in the forests, to checking erosion, to road making and vermin destruction in the national parks, to various forms of reclamation and salvage work—the corps itself being the most magnificent piece of human salvage this generation has known. One cannot but think that it would be of value to the population of Britain if all our young men could be conscripted for six months of their life to carry out public work for the improvement of our countryside.

The examples of erosion so far considered are due to the unthinking exploitations of the soil by civilized men. Similar destruction of the land is, however, taking place in Africa, where the tribes have not arrived at a system of farming that conserves the fertility of the soil, but practise the more primitive form of 'shifting cultivation'. The cultivator is allotted a particular plot in the area of jungle or bush belonging to his clan; this he, or rather his wives, clears, perhaps burning off the timber before putting in his crop. In two or three years the soil begins to become exhausted or weeds become intractable, whereupon the plot is abandoned and a new piece is taken up. The abandoned plot is soon covered with the natural vegetation, and in the course of time, perhaps ten, perhaps thirty years, recovers sufficiently to be ready to take into cultivation again. Thus the tribe requires many times as large an acreage of land as is actually in cultivation at any one time, and if the tribe is increasing in numbers it will be eating pretty steadily into hitherto unoccupied grassland or forest.

One other feature is of importance. The Bantu tribes, who predominate in East Africa, attach the greatest value to livestock, particularly to cattle. Cattle represent wealth and position; they are intimately bound up in tribal custom with the marriage ceremonies—indeed they enjoy a definitely religious status. They are the essential consideration that has to be tendered for a wife. But they serve little or no economic purpose. They are not eaten except ceremonially, by many tribes, they are not milked, they are not beasts of burden, neither is their dung used as manure. Sheep and goats are in the same category; they are less sacred and less valuable; their only economic product is their skins for clothing.

Consider the consequences: within this century British rule has maintained peace among the tribes, and with the cessation of raiding, numbers have been rising steadily. According to census returns, the native population in the Union of South Africa has doubled in the last fifty years; in Basutoland the estimated population multiplied fourfold between 1879 and 1921. In Kenya the annual rate of increase is estimated at about 1½ per cent, which means doubling the numbers in forty-six years, and similar estimates are made for the Nandi tribes in the Kavirondo and for the Uganda population.

The increase of human population has been accompanied by an even greater increase in the numbers of livestock, which in the old days had been effectively kept under by raiding. With these checks gone, the animal population has outgrown the means of sustenance, and even in some districts is destroying the vegetation in uncultivated areas which should be regenerating against their turn to be brought into cultivation. The Native Economic Commission of South Africa, reporting in 1932, stated: "With the exception of certain parts of Zululand and Pondoland every native area is overstocked", and estimates that between 1918 and 1930 cattle increased from 7 to 17 hundred thousand, and sheep from 2½ to nearly 4 million. The Kenya Land Commission, reporting in 1933, wrote: "Probably about 1920 the main stock areas of the native reserves had attained their optimum carrying capacity, and although fully stocked, were not overstocked. Since then the cattle population has—roughly speaking—doubled itself". Again, of the Kamba reserve: "Mr. Scott Little estimates that the reserve contains 190,000 cattle with 57,000 calves, though he estimates its grazing capacity at no more than 60,000 head. There are also 260,000 goats and 150,000 sheep. A journey through the area east and south of Machakos reveals that over large stretches of hillsides vegetation has been almost wholly removed. The soil has been eroded down to the subsoil and its removal will continue at an ever-increasing rate. On less steep slopes and on better land vegetation still persists, and though the Wakamba are primarily a pastoral tribe, patches of cultivation are in evidence. But even there grazing has been so persistent that the ground is all beaten down into little stock paths and has become in turn open to erosion".

Mr. C. W. Hobley, giving evidence about Tanganyika, said: "The native occupier, if space permits, moves on, leaving exhausted soil and desert behind him". Prof. E. P. Stebbing has uttered strong warnings of the encroachment of the Sahara upon northern Nigeria, due to shifting cultivation and overstocking in the forest. Major Grogan put the matter brutally when he said before the Kenya Land Commission: "The African people have never established a symbiotic relationship with land. They are, in the strict scientific sense, parasites on the land, all of them", and in another place he speaks of flying over Central Africa and picking out the eroded areas by their colour.

These instances will suffice; over a large part of Africa—the eastern side from the Abyssinian frontier down to the Cape, Uganda and parts of Nigeria, everywhere indeed except in the tropical rain-forest of the western seaboard and interior—conditions are such as render erosion by washing a danger. Further, there is a native population practising a destructive form of agriculture and keeping a vast uneconomic head of stock, including the devastating goat in large numbers; they are eating rapidly into such forest areas as are left open. Small wonder that famine is never far away from some of the tribes, that the major political issue between native and white man is the cry for more land. Yet even if there were more land to give, the day of reckoning would only be deferred, the new land would only be eaten up in its turn; the native must either change his methods or limit his numbers. Indeed, the situation has even now gone so far that from time to time the Government has to import food to save a tribe from starvation.

It is but recently that the dangers of erosion in Africa have come to be realized. However, it is now evident that all the African colonies have become erosion conscious, as may be seen from Sir Frank Stockdale's report on his recent tour through Africa.

Much yet remains to be done before the arrears of years of misuse of the soil can be repaired and before the native population can be educated to systems of farming which will maintain the fertility of the land. Not only have drastic changes in native custom to be brought about, but also in many cases expenditure is called for which can scarcely be found within the limited resources of the particular colony.

The regeneration of wasted areas must begin with closing them for a time to grazing, so as to allow the return of natural vegetation; if the land has not been very badly denuded, recovery is rapid; but in places it may be necessary to introduce specially useful plants like the stoloniferous grasses so characteristic of South Africa. A certain amount of minor engineering is needed to check run-offs and dongas by dams or plantations. Measures to deal with the invading weeds like *Striga* in Central Africa or the *Chrysocoma* of the south are still lacking. At the same time cultivators, both natives and white settlers, are being taught the virtues of contour ploughing and planting, and of vegetation strips in cultivated land to break up run-off.

Such measures, however, do not touch the major cause of erosion—overstocking. Legislative action is necessary to compel a reduction in the head of stock. The drastic culling that is called for must be done by way of purchase, and since the animals which would first be drafted are practically valueless for food, one or more meat factories would be required to turn the carcasses into manure and then into successively better products as the quality of the culls improved. A reduction in the numbers of cattle or sheep to one half or so would not only relieve the pressure on the land but also would give the native owners some chance of improving quality both by selection and by better feeding, whereas at present numbers alone are valued. Education should also proceed to induce the natives to use cattle economically for milk or meat and for traction, or at least to sell them for food.

Even more fundamental must be the education of the natives to adopt a conservative system of farming—a rotation that would include leguminous crops and so help the native dietary as well as restore nitrogen to the soil. Compost-making is another method of maintaining fertility which is being taught to the natives. The African cannot increase, cannot even maintain, his present numbers unless he learns how to use his plot of land so that it will continuously produce food.

But it is difficult to speak temperately of the urgent need for effort in this direction on a large scale. Many of the tribes are on the verge of starvation, the desert is growing apace, and as the cropping or grazing area shrinks, the pressure upon it becomes greater, and destruction proceeds at a compound interest rate.

The responsibility for action lies not only on the Colonial Governments but also on the British Government itself. It has declared itself trustee for the native populations; it must save them from themselves. Other nations are demanding colonies in Africa as sources of raw materials and as openings for colonization, but as soon as one gets away from the few mineral areas African land affords little opportunity of exploitation, and will indeed only continue to exist productively if its overlords adopt and persist in a self-denying policy.

Cobalt and Copper in Ruminant Nutrition

By Hedley R. Marston, E. W. Lines, R. Grenfell Thomas and I. W. McDonald
Council for Scientific and Industrial Research (Australia), Nutrition Laboratory,
University of Adelaide

As the successful use of supplements containing cobalt for the prevention of bush sickness in stock has given rise to a considerable amount of publicity in which the original source of information has been largely lost sight of, a brief résumé of the sequence of events that led to this application seems desirable.

The apparently essential nature of cobalt in the nutrition of ruminants was first suggested by a group of workers in the Council for Scientific and Industrial Research Nutrition Laboratory in the University of Adelaide, from experimental findings during the investigation of the etiology of 'coast disease', a malady which affects sheep confined in their grazing to the highly calcareous shell sand littoral of southern Australia. The dramatic response and rapid restoration observed to supervene when minute amounts of cobalt (1 mgm. a day as soluble salt) were administered to seriously affected animals was announced at the Australian and New Zealand Association for Advancement of Science during the January meeting in 1935, when the close resemblance that coast disease bore to stock ailments known in different parts of the world as bush sickness (New Zealand), enzootic marasmus (Western Australia), pine (Cheviots and Inner Hebrides), nakaturuitis (Kenya), and salt sickness (Florida), was again stressed. This address was published a few months later.

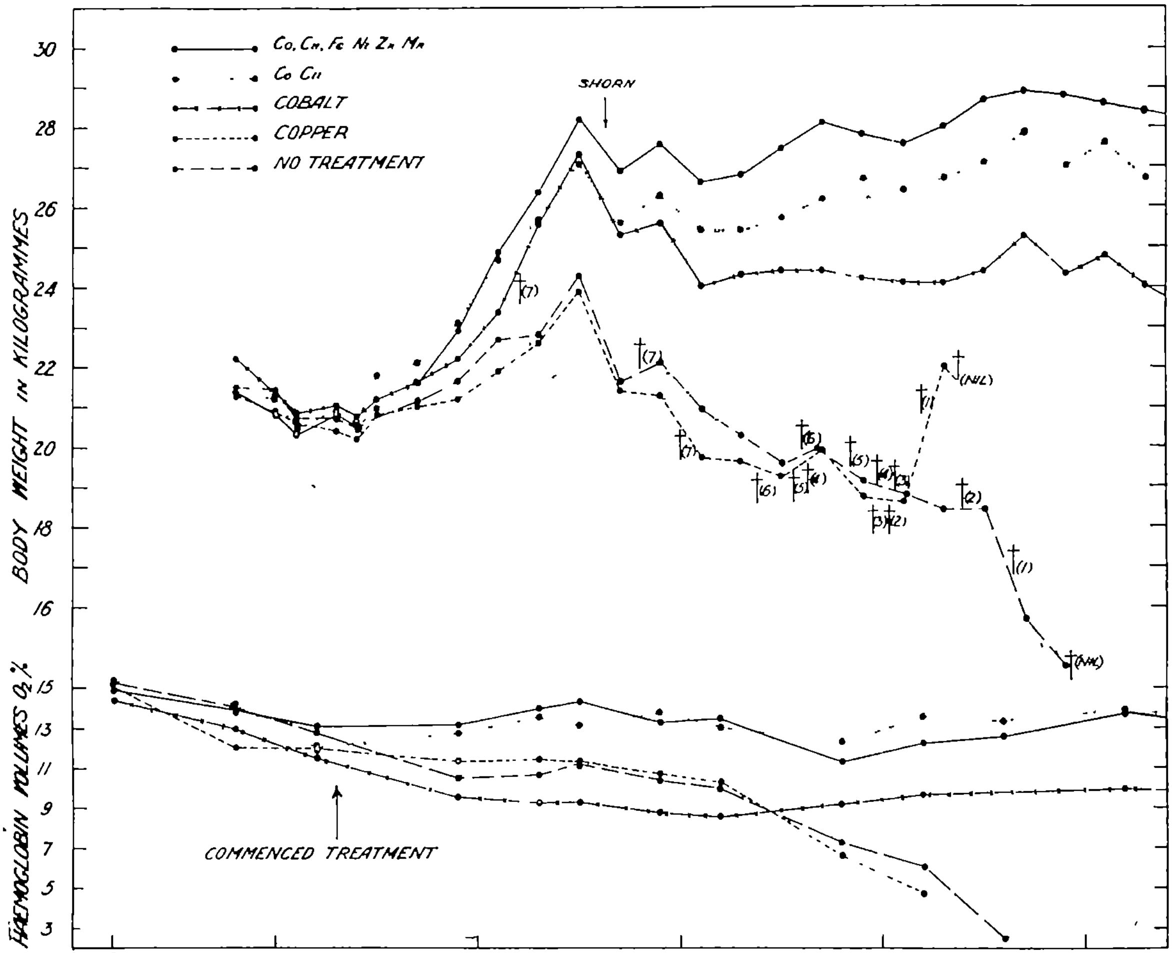
The appearance of symptoms of lethargy, progressive wasting and anæmia in ruminants confined to certain restricted areas, and their rapid alleviation if the affected flocks are changed to a different type of country, has been recognized for many years. The description in 1807 of pining, daizing or vinkish by the Ettrick shepherd, James Hogg, suggests that this malady results from a deficiency, for the ". . . distemper . . . affects sheep confined to some districts . . . but removing them to fine land cures them immediately". The symptoms he reported later (1831) are those commonly recognized in the diseases mentioned above. McGowan and Smith's study of the distribution of pine disease in areas derived from porphorytic rocks on the Scottish side of the Cheviots, and Grieg and Dyrerre's investigation of the lethargic wasting as it occurs among sheep grazing exclusively on the shell sand beaches of the Isle of Tiree, led to the recognition of its similarity to bush sickness.

The New Zealand bush sickness, which occurs in areas usually defined by relatively recent volcanic showers, was referred to in the early reports of Park (1806) and later by Gilruth (1900). Guided by the hypothesis that the associated anæmia resulted from iron deficiency, Aston and his collaborators observed the benefit which followed dosing affected animals with massive amounts of iron salts, which, in the light of our present knowledge, it seems probable were contaminated with traces of other elements. For economic reasons, Aston suggested the use of the naturally occurring hydrated iron oxide, limonite, and this material, providing it originated from certain deposits, undoubtedly helped to control the disease.

The investigations of Filmer (1933) of a similar malady, enzootic marasmus, affecting both cattle and sheep grazed continually over certain highly ferruginous sandy loams of the Denmark district of Western Australia, led to the conclusion that while large doses of limonite prevented the occurrence of the malady and restored affected animals to normal health, pure iron salts were ineffective. Later, Filmer, in collaboration with Underwood, found hydrochloric acid extracts of limonite to be as active as the material itself, and the potency of these was unimpaired on removal of all but the faintest traces of iron. Underwood fractionated these extracts further ; but, owing to the vagaries of the chemical methods and his dependence on so-called pure chemicals, the issue was temporally obscured.

Meanwhile, the investigations of coast disease had proved that therapy with carefully purified iron salts, either alone or in conjunction with copper and with liver extract, failed to arrest the progress of the symptoms. The maintenance of health of sheep which had free access to a complex salt mixture containing cobalt while pastured on affected country was observed, and the publication of the production of polycythæmia in rats by minute amounts of cobalt by the Walthners, led to the experiments that resulted in the immediate response which cobalt therapy brought about in animals suffering from coast disease. The implication that sheep suffering from enzootic marasmus would react similarly to cobalt was amply confirmed by Underwood and Filmer's demonstration following a short visit of Dr. Underwood to the Nutrition Laboratory, Adelaide, that small doses of cobalt rapidly restored affected animals to normal health.

Reports of the variability of the response of bush sick animals to treatment with massive doses of limonite or of soluble iron salts led to the conclusion that Aston's iron deficiency hypothesis, although vigorously defended, was untenable. Rigg and Askew were unable to find a significant difference in the iron content of pastures from bush sick and healthy areas. They demonstrated later that iron-free extracts from healthy soils would completely prevent the onset of untoward symptoms in sheep grazing on bush sick country. Following the announcement of the effect which cobalt exerted on animals suffering from coast disease, Askew and Dixon (1936) demonstrated that cobalt supplements were completely effective as a preventive and cure of bush sickness as it occurs at Morton Mains, and since then the treatment has been widely applied with obvious success in New Zealand.



THE DEATH OF AN ANIMAL IS INDICATED BY A CROSS AND NUMBERS IN BRACKETS SHOW NUMBER OF SURVIVORS IN THE GROUP

Effect of cobalt and copper on young sheep depastured on the littoral where coast disease occurs. Each matched group contains eight lambs aged 8 months at beginning of the experiment. All were depastured together, the treated groups receiving their supplements in aqueous solution three times weekly. The symptoms appear after about 20 weeks and account for all which do not receive cobalt in about 50 weeks. The incapacity of copper when administered alone to prevent the progress of the symptoms and its effect when superimposed on cobalt treatment is obvious.

Reproduced from *Bull. Council Sci. Ind. Research* (*Australia*). (Marston and McDonald).

The part undoubtedly played by cobalt in restoring and maintaining health in sheep suffering from the three maladies, coast disease, bush sickness, and enzootic marasmus, which although strictly regional, occur in markedly different terrain, suggests that pine, nakaturuitis and salt sickness, which apparently evidence identical symptoms, may be the result of a breakdown in the chain of metabolic events for which cobalt provides a link; or not unlikely, they may indeed be of identical etiology, resulting from a metabolic disturbance caused directly from a partial or absolute shortage of cobalt in the fodder of the affected areas.

Coast disease, in some regions, is a rather more complicated syndrome than that resulting from cobalt deficiency. While it shares the symptoms of lethargy, wasting and anæmia with the other maladies which respond to a small supplement of cobalt, sporadic outbreaks of ataxia are frequently observed in young lambs born of ewes which have spent a relatively short sojourn during their pregnancy on certain parts of the littoral.

This condition, which results from degenerative changes in the spinal cord, although strictly regional also, is not invariably confined to areas where coast disease is enzootic. While the resulting lesions of demyelination are anatomically related to those observed in the enzootic paraplegia (renguerra) reported to occur among lambs bred in certain areas in the Peruvian Andes, and to those of swayback, which accounts from time to time for many lambs in certain parts of England, the underlying cause may possibly be distinct. The similar condition, enzootic ataxia of lambs in the Gin Gin area of Western Australia, which Bennetts has recently attributed to copper deficiency and shown to be overcome if the pregnant ewes on this area are supplemented with small amounts of copper, is, however, apparently closely related etiologically with that observed on the affected littoral; for our experiments have amply demonstrated that small amounts of copper are essential to maintain cobalt-treated animals in good health while depastured on the areas where both ataxia and coast disease occur, notwithstanding the fact that supplementing with copper neither alleviates the symptoms of coast disease nor prevents the appearance of the anæmia and fatal decline if unaccompanied by cobalt.

The findings focus attention again on the possible physiological importance of those traces of elements, usually considered exotic, which have been demonstrated to be constantly present in living tissues, and furthermore, the discovery adds yet another example of the remarkable species difference in the behaviour of living organisms towards the nutritional environment; which, with little doubt, reflects subtle differences in the nature of the underlying metabolic processes.

The fact that horses exhibit no untoward symptoms when confined in their grazing to littoral tracts where ruminants will progressively decline and expire if left unsupplemented with cobalt is at present a fascinating subject for speculation, which may be solved when our knowledge of the role which cobalt assumes in the normal physiological function of some animals is extended.

A full description of the investigations of coast disease appears in monograph form in a Bulletin of the Council for Scientific and Industrial Research (1937). The references in the literature to similar maladies mentioned above are discussed in further detail there.

Obituary Notices

Dr. A. B. Rendle, F.R.S.

ALFRED BARTON RENDLE, who died at Leatherhead on January 11, was one of the leading British systematic botanists, and had been keeper of botany in the British Museum (Natural History) from 1906 until his retirement in 1930.

Born in London on January 19, 1865, he was educated at St. Olave's School, Southwark, and St. John's College, Cambridge, where he studied botany under Vines. In 1888, he was appointed assistant in the Department of Botany in the British Museum (Natural History), being placed in charge of the Monocotyledons and Apetalæ. It was characteristic of Rendle that his first taxonomic paper was not published until five years later, when he had mastered the technique of the subject. His work was consistently thorough, and the fact that he was able to accomplish so much is a tribute to his unremitting industry. As lecturer in botany at the Birkbeck Institute, Rendle kept in touch with academic circles, and in 1904 the first volume of his "Classification of Flowering Plants", comprising the Gymnosperms and Monocotyledons, was published by the Cambridge University Press. He described it modestly in the preface as "an attempt to give the student who has some acquaintance with botany a systematic account of the Flowering plants", but it was much more than this. By consultation of original memoirs as well as works of reference, Rendle had enriched it with many observations relating to embryology, anatomy, ecology, pollination and modes of fruit and seed dispersal, as well as with notes on the more outstanding types found in the various families. The second volume, including the Dicotyledons, appeared in 1925, and a new edition of vol. 1 in 1930.

Rendle fully appreciated the importance of the diffusion of scientific knowledge among the general public, and of closer relations between botanical theory and horticultural practice. He regularly attended the meetings of the British Association, and was president of Section K (Botany) at Newcastle in 1916. His knowledge of exotic floras and vegetation was enlarged by visits to Canada, the United States, Australia, South Africa and Bermuda. For many years he lectured on botany at the Royal Horticultural Society, and he took a great interest in the work of local natural history societies, having been president of the South London Botanical Institute and chairman of the Botanical Section of the South-Eastern Union of Scientific Societies.

Among Rendle's more important early scientific publications were an enumeration of the Monocotyledons and Gymnosperms collected by Welwitsch in Angola (1899), a revision of the genus *Najas* (1899), an account of the family Najadaceæ for Engler's "Pflanzenreich" (1901), and an enumeration of the Gramineæ of China and adjacent areas in Forbes and Hemsley's "Index Floræ Sinensis" (1903). The families on which he worked most were the Gramineæ and Orchidaceæ, though the wide scope of his studies left him no leisure in which to do monographic work in either. A joint paper with William Fawcett on the Jamaican species of *Lepanthes* (1904) was followed by the production, in collaboration with Fawcett, of four volumes of their "Flora of Jamaica", the first of which, comprising the orchids, appeared in 1910 and the fourth in 1926. After Fawcett's death, Rendle completed a fifth volume (Rubiaceæ and Compositæ), the greater part of which had been prepared by Spencer Moore.

Among the wide range of subjects which engaged Rendle's attention were bibliography and nomenclature. His studies on the flora of Jamaica and the grasses led to the appearance of bibliographical notes on Swartz's "Prodromus" (1897), Steudel's "Synopsis Plantarum Glumacearum" (1899) and Browne's "Natural History of Jamaica" (1912). After Britten's death, he edited the *Journal of Botany* (1925–38) and the second edition of Britten and Boulger's "Biographical Index of Deceased British and Irish Botanists" (1931).

The world-wide interest in the thorny subject of botanical nomenclature aroused by the publications of Otto Kuntze and other reformers led to the formulation of various proposals for alteration of the Paris "Lois de la Nomenclature botanique" (1867). Those from the British Museum (Natural History) were communicated to the Vienna Congress (1905) by Rendle, who attended the meetings as delegate for the Linnean Society as well as for the Museum Department of Botany. He served as a member of the editorial committee of the International Rules of Botanical Nomenclature in 1905–1935, and was responsible for the English text of the third edition of the Rules.

Rendle became a fellow of the Linnean Society of London in 1888 and served for three periods on the Council before his election as secretary in 1916–23 and president in 1923–27. He regularly attended the Society's meetings, taking part in the discussions and contributing numerous papers to the *Journal* (*Botany*) and *Transactions*. He was elected a fellow of the Royal Society in 1909.

The keynote of Rendle's career was conscientious performance of duty. Whatever came to his hand, he did it.

T. A. S.

Prof. A. V. Martynov

ANDREI VASSILIEVITCH MARTYNOV, whose death occurred on January 28, was born in 1879 in Riazan, Central Russia. After graduating at the University of Moscow, he became an assistant professor in the University of Warsaw, then a zoologist in the Zoological Museum at the Academy of Sciences in Leningrad, and finally professor in the new Institute of Palæontology of the U.S.S.R. Academy of Sciences at Moscow.

The scientific work of Martynov in the earlier period was mainly concerned with the study of the systematics and zoogeography of Trichoptera (caddis-flies), in which group he was one of the leading experts and on which he published several first-class monographs and a very large number of papers. This work led him to broader studies in insect morphology, more particularly in investigations of wing venation from an evolutionary point of view, and in this direction he made most important contributions to entomological science. Later, he turned his attention to the study of fossil insects, again with brilliant results (see below). As an indication of his unusual ability and energy, it should be mentioned that he also found time to work on the systematics of the Crustacea (particularly Gammaridæ), on which group he produced several important works.

A characteristic feature of all taxonomic researches by Martynov was his persistent seeking for the better understanding of the problem, with the aid not of morphology alone, but also of the ecology and the distribution of the animals studied. For his researches he was awarded the degree of doctor of biological sciences by the U.S.S.R. Academy, while the Société Entomologique Belge and the Russian Entomological Society elected him an honorary member.

Owing to the extensive circle of his interests, Prof. Martynov, although he had never been abroad, was probably one of the most widely known Russian entomologists, and his premature death will be felt deeply throughout the entomological world.

B. P. UVAROV.

As a palæo-entomologist, A. V. Martynov had an international reputation. His palæontological work was devoted entirely to the fossil insect deposits of Russia, among which those of the Permian of Tikhiye Gory and those of the Jurassic beds of Turkestan (Kara Tau) deserve special mention. From these and many other localities, Martynov described, in about forty publications, a great number of new forms, many of them of considerable phylogenetic importance. In particular, it was his work on the Permian insects which made Martynov widely known and brought him into close contact with the late Dr. R. J. Tillyard, who worked on the Permian insects of Australia and of Kansas, and with Carpenter, who is investigating the Kansas fauna. Before Martynov's studies in fossil insects, almost nothing was known from Russian territory. Now, after his premature death, Russia occupies a prominent place in palæo-entomology, and this is entirely due to Martynov's energy. His qualifications as a systematist appear in his careful descriptions, which will always retain their high value, even if in some cases his classification may have to be modified in future.

Martynov was able to trace backwards to earlier times the phylogeny of several groups of insects. He contributed a great deal to the knowledge of Permian Hemiptera, Mecoptera, Coleoptera, Odonata and other orders, and he described Phasmatodea and earwigs from Jurassic strata. The relations of these Permian and Jurassic forms to those of other countries were of special interest to him. He found close connexions between the Permian insects of Kansas and Russia, whilst the Jurassic fauna proved to be of an 'Angaran' type, with Indo-Australian relations.

There is no doubt that by Martynov's death palæo-entomology has suffered a severe loss and that his name and work will play an important part in research for a long time to come. F. E. ZEUNER.

Mr. D. Baxandall

MR. DAVID BAXANDALL, who recently retired from the position of deputy keeper at the Science Museum, passed away on January 10 at the age of sixty-three years, after a short illness.

Born on April 9, 1874, at Haworth, near Keighley, Mr. Baxandall received his early training at the Keighley Institute, where in 1891 he succeeded in winning a Royal Scholarship with which he proceeded to the Royal College of Science at South Kensington. Here he studied mechanics under Henrici and in 1894 obtained his first-class associateship in mechanics. He remained at the College for a further period during which he assisted Lockyer, until in 1898 he entered the Science Museum. During his first years at the Museum, he was employed in the Machinery and Inventions Division, but afterwards he was transferred to the Science Division, where he quickly developed a keen interest in early scientific instruments. He also studied the activities of early scientific instrument makers, and became a leading authority on this subject. Although Mr. Baxandall had a good knowledge of all kinds of scientific instruments, it was to astronomical, optical and mathematical instruments that he devoted his greatest attention, and it is chiefly due to his unremitting efforts that these subjects are so well represented in the Science Museum.

Mr. Baxandall was quiet and unassuming in manner, and although he was a fellow of the Royal Astronomical Society and of the Optical Society for many years, he was of such a retiring disposition that it was only with difficulty that he could be persuaded to speak at the meetings. He presented a number of papers on historical instruments and instrument makers before these Societies, and also contributed several articles to the "Encyclopædia Britannica".

By far the greater part of Baxandall's work, however, remains unpublished, for he collected together a large amount of valuable information on early instrument makers and their products, which he was hoping to prepare for publication, but unfortunately he was not able to complete the work. At the time of his retirement in 1934 he was deputy keeper in charge of the Science Division of the Science Museum, a position he had held for more than twelve years. He leaves a wife and two sons to mourn his loss, but he will be remembered with respect and affection by all who were privileged to know him as their friend.

Prof. Gustav Jäger

IN Gustav Jäger, whose death at seventy-three years of age occurred on January 21, Vienna has lost one of the last men who linked present-day physics with the classical period of the Viennese school as represented by the names of Stefan, Loschmidt and Boltzmann, and moreover one who had an unusually wide and all-round knowledge of physics. After several years of study in the laboratories of Stefan in Vienna and Helmholtz and Kundt in Berlin, he became assistant first to Stefan and later to Boltzmann. In 1905, he was appointed professor at the Technische Hochschule in Vienna, and then was called in 1918 to fill the chair of theoretical physics at the University of Vienna, which had formerly been held successively by Stefan, Boltzmann and Hasenohrl. In 1920, Jäger changed this chair for the directorship of one of the University institutes of experimental physics. Generations of students have listened to his lecture courses, and greater still is the number of those who were introduced to the elements of mathematical physics through his "Theoretische Physik", published in the handy volumes of the "Sammlung Goschen", and distinguished by clarity as well as conciseness.

In his original contributions to physics, Jäger showed himself a true pupil of Loschmidt and Boltzmann by his life-long interest in the problems of the kinetic theory of matter. Best known among his papers are probably those devoted to the development of a kinetic theory of 'ideal liquids', analogous to that of 'ideal gases'. That his occupation with technical problems bore fruit is shown, for example, by his contributions to the theory of aircraft construction; he was one of the earliest men of science who defended, on theoretical grounds, the possibility of heavier-than-air flying machines.

Jäger retired from his chair of physics in 1934, but as a member of the Vienna Academy of Sciences remained to the last in touch with scientific matters. His death is deplored by a great number of friends and colleagues, who will miss his amiable and cultured personality and his sound and balanced judgment.

F. A. P.

WE regret to announce the following deaths:

Mr. Thomas Gann, known for his explorations in Central America and his investigations of Maya archæology, on February 24, aged seventy years.

Dr. George Ellery Hale, For.Mem.R.S., honorary director of the Mount Wilson Observatory, Pasadena, California, on February 22, aged sixty-nine years.

News and Views

Prof. W. L. Bragg, O.B.E., F.R.S.

THE election of a successor to the late Lord Rutherford in the Cavendish chair of experimental physics in the University of Cambridge has been eagerly awaited by men of science all over the world, and it may safely be said that the appointment of Prof. William Lawrence Bragg, Director of the National Physical Laboratory, will give widespread satisfaction. Prof. Bragg shares with his father, Sir William Bragg, president of the Royal Society and director of the Royal Institution, the credit of founding the science of crystal structure which has grown in the last twenty-five years until it affects almost every branch of science, and dominates several. This work, a consequence of von Laue's discovery, was begun shortly after W. L. Bragg took his degree in 1912, and so rapid was the progress until the outbreak of the Great War that father and son were jointly awarded the Nobel Prize in Physics in 1915. During the War, Bragg made a great reputation as the leader and virtual creator of the British sound-ranging service which was generally admitted to have been consistently in advance of that of any other army. In this work, he showed both scientific and organizing abilities of the highest order, and led a group of men of whom many are famous in science to-day. Returning to Cambridge after the War, he was appointed in 1919 to succeed Rutherford in the Langworthy chair of physics in the University of Manchester, and proceeded to build up a school of workers with whose aid he disentangled crystal structures of ever-increasing complexity. His work on the silicates may be regarded as the culmination of this phase. Bragg possesses to a quite exceptional degree the power of thinking in the solid, and those who have worked under him speak with awe of his uncanny instinct for seeing the way in which a collection of atoms will group themselves.

IN recent years, Prof. Bragg has turned his attention to alloys, and by the application of the idea of co-operative action to the arrangement of atoms—the 'order-disorder' theory—has made important progress in this difficult, tangled subject. The study of atomic arrangements touches a surprising number of practical problems. Besides that of the invention of useful alloys, one may instance the agricultural properties of clays and recent developments in the study of proteins. It is possible, therefore, that under its new head the work of the Cavendish Laboratory may come into even closer contact with everyday life. It is only last year that Bragg was appointed director of the National Physical Laboratory (see NATURE, 139, 830; 1937), and it must have been difficult to face another change so soon; but the powers of organization and the personal qualities which made him so suitable a head for a large body of research workers will be of equal value at Cambridge. The Cavendish Laboratory is now so large that no one man can control it all closely, and Bragg's tact and gift of leadership form the best possible assurance of the happy co-operation of its many groups of research workers, while his brilliant lectures and personal charm ensure his success as a teacher of undergraduates.

Prof. G. M. Bennett

PROF. G. M. BENNETT, Firth professor of chemistry in the University of Sheffield, has been appointed University professor of chemistry in King's College, London. Prof. Bennett's researches have been of varied character. Some, such as those concerning the synthesis of penthiane derivatives, the nature of the polymeric ethylene sulphides and the derivatives of monothioethyleneglycol have dealt with subjects of particular interest in the chemistry of organic sulphur compounds. Among others of more general interest, his study of the stereoisomerism of di- and tri-sulphoxides is noteworthy; this revealed the existence of isomeric di-sulphoxides derived from substances such as ethylene disulphide, thianthrene and the ethers of dithioethyleneglycol, and it culminated in the isolation of the five oxides derived from trimethylenetrisulphide, an absolute proof of their stereochemical structures being obtained from their relationships. Another group of Prof. Bennett's researches has dealt with the variation in reactivity of a group under the influence of others present in the molecule. These began with a quantitative study of the influence of sulphur or oxygen on the reactivity of halogens or of the hydroxy group separated from the former by a lengthening chain of saturated carbon. The data then obtained and their theoretical interpretation led to experiments dealing with the general influence of nuclear halogens on aromatic side-chain reactivity; these led to the view that the electromeric effects of the halogens vary in intensity in an order which is opposite to that previously accepted. More recently, Prof. Bennett has made a study of organic molecular compounds and as a result has found justification for the view that in many of these the components are united by some form of a true valency bond. Adoption of this view led to the discovery that other electron-attracting groups such as cyanogen, methane sulphonyl, and chlorocarbonyl may serve instead of the usual nitro-group in one of the components.

Gustav Fritsch (1838–1927)

GUSTAV THEODOR FRITSCH, a pioneer in the physiology of the brain and one of the last great personalities of the classic period of German medicine, was born on March 5, 1838. He received his medical education at the Universities of Berlin, Breslau and Heidelberg under Helmholtz, Peters, Traube, Frerichs and Langenbeck among others, and qualified with a thesis on the central nervous system in 1862. He then spent three years in extensive foreign travel. In South Africa he made a study of the anatomy and physiology of the natives. He then visited Aden, where he studied eclipses and passed on to Upper Egypt, where he made some important anthropological and ethnographical investigations. On his return to Germany he devoted himself to the study of diatoms and electric fishes, and in 1868 was made assistant to Prof. Reichert at the Berlin Anatomical Institute. His chief achievement was the discovery in 1870 in collaboration with Hitzig of the motor centres of the cerebral convex and their excitability by the faradic current, which formed one of the landmarks in the history of physiology. In 1908, at the age of seventy years, he published a remarkable work on the comparative racial morphology of the human retina, illustrated by plates prepared from photomicrographs, in which, as in scientific photography generally, he had always shown a keen interest. His death took place on June 12, 1927.

Native Policy in the Union of South Africa

THE arguments in favour of the transfer of the South African Protectorates to the Union of South Africa without further delay were stated ably and perspicuously by Mr. Lionel Curtis in his address to the Royal Empire Society on February 8. He pointed out that such a demand was inevitable on the formation of a National Government, which with its party is bound to consider how far the control it exercises in its domestic affairs, under the law as expressed in the Statute of Westminster, is effective. In such a survey, it is forced on their notice that the inhabitants of the Protectorates are dependent upon the Union territories for the sale of their produce and further a great proportion of them earn their living within the Union. Socially and economically the Protectorates, therefore, are integral parts of the Union. The relations of white to black lie at the root of all South African questions; and it is idle to tell the South African Government that it has been given complete control of its domestic interests so long as they lack control of areas, which, beyond dispute, are component parts of its social and economic community. Mr. Curtis then recited the changed conditions which have been brought about by the Balfour Memorandum and the Statute of Westminster, and argued that in view of that change it is no longer possible to meet the demand for transfer with the reply that it cannot take place until South Africa's native policy within the Union has conformed to British opinion. Not only is he not of the opinion that the interests of the natives throughout South Africa would be best served by withholding the transfer; but he also considers such a policy fraught with disaster. Noting the growth of a reaction against the prevailing opinion on native policy among young Afrikanders in the universities, he concluded by urging that the time is over-ripe for discussion of the transfer, consultation of the natives to form part of that discussion.

THE views expressed by Mr. Curtis have aroused no little criticism. This has served to indicate once more that there is a considerable body of opinion in Great Britain which attaches overwhelming importance to the obligation of the British Government to carry out its pledges—pledges both to the Union of South Africa, as well as to the natives of the South African Protectorates. No one has ventured to suggest that the transfer should be delayed indefinitely; but on the other hand, it is certain that instructed opinion would favour decisively the view expressed by Lord Lugard that some further delay is desirable. It is, however, no less essential that, if there is to be further delay, it should be secured by such means as will avoid hardening public opinion, which is steadily growing in South Africa against the tendency towards a more liberal policy in native affairs. The number of advocates of what may be termed, for brevity, 'the anthropological approach' is increasing, and the influence of the universities in leavening public opinion by the objective, non-political and scientific study of a difficult social problem is becoming stronger. In the long run, this leaven is bound to tell; and time is in its favour. In the last resort, however, the solution lies with the Union Government. When its native policy becomes such that it is acceptable, not as is suggested to opinion in Great Britain, but to the natives of the Protectorates, and wins, if not their assent, at least not their active and stubborn opposition, the time for transfer will have come. The acerbity of the argument in favour of immediate transfer put forward by some of its supporters argues a knowledge that reference to the native population at the moment would meet with an unfavourable reply.

Closing Excavations at Maiden Castle, Dorchester

THERE is a dramatic touch in the discoveries of the fourth and final season of joint excavation by the Society of Antiquaries of London and the Dorset Natural History and Archæological Society on Maiden Castle, which in other circumstances it would be difficult to accept as entirely fortuitous. Dr. R. E. Mortimer Wheeler, in describing his recent finds on this site before the Society of Antiquaries on February 23, was able to give a detailed account of the final assault on, and dismantling of, the fortress by the enraged troops of Vespasian in A.D. 43, which was not merely an imaginative reconstruction derived from topographical observation, but was also a direct inference from the evidence of such archæological finds as projectiles from the barrage of the field train of artillery, which preceded the attack, the ruins of the platforms or towers protecting the approaches, and the ashes of the burnt hutments outside the walls, in which were found the burials, hurried and confused as if interment had taken place in the night following the battle, of the defenders, whose bodies had been savagely hacked by the attacking soldiers. Then followed the evidence of the period of British occupation of the site as an open town, until the inhabitants were removed to the neighbouring Roman city, recently founded, where Dorchester now stands, and Maiden Castle was left waste, except for an isolated burial of a Saxon warrior in the seventh century, which brings the story of Maiden Castle to a close. Though less dramatic, two discoveries relating to the neolithic period are almost equally important as confirming Maiden Castle's position as a classic reference in British prehistory. Of these, one was a crudely shaped chalk idol of the Mediterranean mother-goddess type, "an interesting and rare addition to the equipment of neolithic Britain"; and secondly a vast mound of later neolithic age, the largest of its kind as yet known, in one part of which was the skeleton of a young man with skull and long bones so hacked soon after death as to afford indubitable evidence of cannibalism.

Expedition to Northern Syria

MEMBERS of the joint expedition of the British Museum and the British School of Archæology in Iraq have left England for a fourth season of excavation on the archæological site of Tal Brak in north-east Syria. The expedition is in the charge of Mr. M. E. L. Mallowan, field director. He is accompanied by Colonel A. H. Burn, Mr. G. H. Bell, who is the architect of the expedition, and Mr. I. Threlfall. The excavations of previous seasons have shown that this site is especially remarkable for its evidence of early relations with Sumeria, and for its affinity with Hittite culture. This year the members of the expedition will continue the examination of a palace, which was laid out on an extensive scale under the dynasty of Sargon of Akkad about 2600 B.C. At the close of last season seven treasure chambers had been brought to light, but their examination had to be postponed as their condition was considered to be unsafe. Their investigation will now be resumed. The work of the expedition, however, will be directed more particularly to the remains of about the period 1500 B.C., when there was a considerable Hurrian population in the Khabur valley in close touch with both the cities on the Tigris to the east and with the Mediterranean coast to the west.

Twenty Years Progress in Science in the U.S.S.R.

THE twentieth anniversary of revolution is marked by the U.S.S.R. Academy of Sciences in the issue of special numbers of its periodical publications. The "Vestnik" of the Academy for October–November 1937 is a volume of 346 pages containing brief accounts of the work during the last twenty years of many, but not all, of the scientific institutes, museums and laboratories connected with the Academy. The number of such institutions has grown from 39 in 1917 to well over a hundred in 1937, with more than 4,000 on the scientific and technical staff as against 212. The October part of "Priroda" (published in January 1938) contains a series of brief surveys of twenty years progress in different branches of sciences, namely, mathematics, astronomy, physics, aerodynamics, chemistry, geology, petrography, botany, physiology, zoology (separate articles on ornithology, mammology, ichthyology, entomology, ecology), palæontology, etc. Many of the articles have a broader basis and treat in a concise form the Russian contributions to the progress of science not only during the 'Stalin's era', as the period 1917–1937 is somewhat inexactly termed in the leading article, but also in the years before the revolution. Indeed, the work of such veterans of Russian science as the astronomer Struve, physicist Lebedev, the great Mendeléeff, physiologist Vvedensky, zoologists Menzbier and Sushkin, etc., is given fullest credit, and it is shown how their ideas have been developed by their numerous pupils and followers in later years.

Official Tests of Composite Aircraft

THE combined seaplane *Mercury* and flying boat *Maia*, designed by Major Mayo and built by Messrs. Short Bros. of Rochester, mentioned in NATURE of February 19, p. 321, passed the first properly observed separation trial on February 23. The actual operation was photographed with a cine-camera from another flying boat flying parallel with it, and knowing the exposure times, accurate measurements of the rate and angles of separation can be made. Subsequent views on the film show that the parting was instantaneous and that the gap widened steadily enough to ensure safety under all reasonable air conditions. The test were not quite the most severe, as *Mercury* was not fully loaded with petrol, having only about half her capacity on board. This reduction of weight is necessary to allow a safe landing. Normally most of the fuel would be consumed during the flight, or in an emergency it can be jettisoned. During the take off, the control is entirely in the hands of the pilot of the lower component, the flying controls of the upper machine being locked by the same mechanism that attaches the two machines. When he wishes to separate, he informs the upper pilot by telephone, waits for an agreed number of seconds, and pulls a lever that releases both the upper machine and its controls. The lower flying boat is trimmed so that it automatically becomes nose heavy when released and dips away, while the upper seaplane, at its best climbing attitude, climbs rapidly. The separation took place at about 800 feet height, flying at 140 miles an hour. These figures could probably be increased considerably should bumpy conditions in the air demand it. It is understood that both pilots, Mr. Lankester Parker and Mr. H. L. Piper, considered the tests to be satisfactory.

Alchemy in Scotland

IN a lecture given on February 4 at Marischal College, Aberdeen, before the local sections of the Institute of Chemistry and the Society of Chemical Industry, Prof. John Read of the University of St. Andrews gave an account of alchemy in Scotland. James IV of Scotland appointed an Italian, John Damian, as his court alchemist, a laboratory being founded in Stirling Castle about 1500. Accounts of the Lord High Treasurer from 1501 until 1513 contain information about the costs of the materials used by Damian and his associates in their attempts to prepare the "quinta essentia", which ended when the King was killed at Flodden Field in 1513. Alexander Seton, who is said to have travelled from Scotland to the Continent in 1602 and to have performed a series of transmutations in various German towns, was tortured by the Elector of Saxony and was rescued by the Polish nobleman Michael Sendivogius, but died in 1604 as a result of the cruel treatment he had received. Seton is said to have been the real author of the "Novum Lumen Chymicum", a work which was regarded as of the highest importance and was even treated with respect by Newton. John Napier, of Merchiston, the inventor of logarithms, was keenly interested in alchemy, as were his father and his son. William Davidson or Davisson, of Aberdeen (1593–1669 ?), was a chemist rather than an alchemist. He became physician to the King of France and wrote an early text-book of chemistry, "Philosophia Pyrotechnia seu Cursus Chymiatricus" (1633–5), which contains one of the earliest contributions to crystallography.

Acquisitions at the British Museum (Natural History)

PRESENTS to the Department of Zoology include the magnificent mounted head (the largest on record) of an Asiatic wapiti presented by Lieut.-Colonel Price Wood, and a very large mounted specimen of a Tasmanian platypus presented by Sir Frank Crisp. Among the specimens presented to the Department of Mineralogy is a fine set of minerals from Western Australia sent by Dr. E. S. Simpson. This includes remarkably large masses of petalite and its alteration products from a feldspar quarry at Londonderry, near Coolgardie. The petalite, a lithium-aluminium-silicate, occurs in masses weighing up to a hundredweight. This is the more remarkable as petalite is one of the rarer minerals and until quite recently was only known as comparatively small crystals. In 1935 and 1936, however, a quarry in pegmatite at Varatrask, Boliden, northern Sweden, yielded many tons of the mineral, and individual crystals were found measuring more than a foot in length. A specimen of this petalite also was presented to the Museum by Prof. P. Quensel. Three fragments of meteoric iron presented by Mr. I. Reinvald, Inspector of Mines, Estonia, are of particular interest as they are part of a lot of about thirty pieces found after laborious search in the neighbourhood of the Lake of Kaalijärv in the island of Oesel. This lake was described in 1827 and many suggestions were made as to its origin. In 1929, Mr. Reinvald made a detailed survey and was convinced that the lake filled a meteorite crater. Five other smaller craters were found in the neighbourhood, but it was only in July 1937 that any meteoric iron was found to confirm the theory of their meteoritic origin. Other specimens received include rocks collected by Dr. J. V. Harrison, and Mr. M. H. Donald on excursions in the Urals and the Caucasus, following the International Geological Congress held in Moscow last year, and special mention should be made of a specimen of carved pyrophyllite from China, presented by Mr. B. Cattell, one of the warders in the Museum.

The Universities Bureau of the British Empire

FROM the Universities Bureau of the British Empire we have received the report of its executive council for 1936–37. Its membership, as at July 31, 1937, comprised the 19 universities of Great Britain and Ireland, 10 of the 21 Canadian universities, 3 of the 5 South African, 6 of the 17 Indian, the Universities of New Zealand, Malta, Hong-Kong and Rangoon, 6 university colleges and 4 other colleges. A resolution was passed by the Indian Inter-university Board last February to the effect that it was desirable that universities in India should join the Bureau. In addition to indicating briefly the various activities of the Bureau during the year, the report enumerates the subjects that were discussed by the Committee of Vice-Chancellors and Principals of the home universities, by the Australian Vice-Chancellor's Committee and by the Inter-university Board, India. The Bureau's Handbook for Students from Overseas published last year had a very wide circulation, and a new edition was prepared in collaboration with the British Council on British Teachers Abroad, which had prepared a somewhat similar manual relating to institutions other than universities. In the new edition, issued as a joint publication by the two bodies, the information has been amalgamated to form an outline of the facilities for higher education provided by universities and other institutions in Great Britain and Ireland.

Centenary of Le Officine Galileo, Florence

IN celebration and commemoration of their centenary, the house of Le Officine Galileo of Florence have issued a striking record of their past and present achievements in the sphere of the manufacture of scientific instruments and other high precision products. They pay tribute also to the men of distinction who have been associated with them and among whom they specially mention the late Marchese Marconi. It has been the privilege of this firm to introduce many instruments of epoch-making importance, and, before 1840, they constructed the circular dividing machine designed by and made to the instructions of Giovan Battista Amici. In 1878, they introduced the Caselli motor for torpedoes. In connexion with astronomical instruments theirs is a long and honourable record; in 1884 they constructed the astronomical clock in the Osservatorio Ximeniano in Florence, and have but recently completed the 1·20 metre telescope for the University of Padua—a model of which was shown at the Paris Exhibition. Among the early examples of their work illustrated in the commemorative volume are an electric automobile of 1900, a military goniometer, an electric field telegraph and the periscope for the Swedish submarine *Hajen* of 1902. An interesting contrast between the old and the new can be observed by comparing the illustrations of the theodolites—the spidery construction of the older type is in complete contradistinction to the compact rigidity of the model of to-day, which illustrates how design of fine measuring instruments has been influenced by the high degree of precision attainable in up-to-date manufacturing processes. Among the types of instruments now being manufactured are to be noted such diverse examples as microtomes, dermato-capillariscopes, stereo-cartographs, polarimeters, binoculars and projectors, while a separate list of electrical apparatus shows oscillographs, radio transmitters, measuring instruments, electric pumps and anti-aircraft equipments.

Radio Waves in the Upper Atmosphere

IN a paper read to the Institution of Electrical Engineers on February 21 by J. P. M. Mellor, it is pointed out that pilot balloons sent up to record the electrical state of the atmosphere have failed as yet to detect any regions of particular interest to the radio engineer. Due chiefly to the increasing use of ultra-short waves for television, some six layers of ionized gas have now been discovered between 4 and 10 miles up. Each layer reflects the ultra-short waves under certain conditions. But they have no effect on the longer waves used in radio communication. Ultra-violet light from the sun ionizes the earth's outer atmosphere to different degrees at different heights; the ionosphere consists of free electrons and positive and negative ions in a rarefied gas. The *D* layer, between 40 and 60 miles above the earth, absorbs or attenuates radio waves. Above this, we have the region of maximum ionization, the Heaviside or *E* layer. Above the 120 mile mark, is the Appleton or *F* layer, which varies in height according to the time of the day. The portion of the energy radiated by the transmitter which travels over the surface of the earth is called the 'ground wave'. The magnetic field penetrates the ground causing eddy currents, thus frittering away the energy of the ray. Attenuation of the ground wave increases as the wave-length is decreased. The 'sky wave' is the wave which is propagated in the atmosphere above the earth. When it reaches an ionized layer, its path is bent earthwards when conditions are favourable. If its frequency is less than the critical frequency the wave is refracted, if equal to it absorption takes place and if greater than the wave it passes through the layer with very little attenuation. A wave sometimes arrives at the receiver after making a large number of ricochets between the ionosphere and the earth. If a receiver is situated close to the transmitter so that it picks up the ground wave and is in the area covered by the reflected wave, then since the waves have travelled different lengths they may interfere with one another and 'fading' will occur. 'Delay echoes' up to three seconds are readily explained by Störmer's electron envelope.

Consumption of Electricity by Wireless Receiving Sets

ACCORDING to the *Beama Journal* of October, wireless, more than any other domestic appliance, familiarizes consumers with electricity and encourages them to become electricity consumers. Quoting from a report of M. Deutsch of Brussels, interesting figures relating to the electricity consumption of wireless sets in various countries are given. The B.B.C. returns the highest estimate, namely, an average annual consumption per set of 87 electric units for a wireless receiver, Belgium, France and Holland return 54 units and Germany 40. In the United States, the consumption per receiver is estimated to be 54. Since the number of mains-operated wireless receivers in the United States was 24 millions at the beginning of 1937, the total consumption due to wireless is therefore nearly 1,300 million units. In Great Britain the number of wireless licences issued at the end of August of this year was more than eight million. A few years ago it was considered that 100 sets per 1,000 inhabitants would be about the maximum. According to M. Deutsch, the existing figure in Great Britain is 160 sets per 1,000 inhabitants, Germany having 120 sets. To-day the maximum is reckoned to be about 300 sets per 1,000 inhabitants. Statistics for 1935–36 show large increases in the number of wireless sets sold in some of the more backward European countries. During this year, Bulgaria increased the number of receivers installed by 91 per cent, Rumania, Portugal, Spain and Poland all registered increases between 30 and 50 per cent. In Great Britain, the increase was 9·2 per cent, whilst in Turkey the figure declined by 10 per cent.

The Oxford Farming Conference

AT the Oxford Farming Conference held on January 4–7 a number of interesting questions of fundamental importance were brought up, and the opening paper—the maintenance of fertility and the land fertility scheme—set the stage for discussions of a far-reaching nature. Although soil deterioration due to erosion or exhaustion of virgin land are not serious problems in England, much of the grassland is in a badly impoverished condition. Drainage, liming, application of phosphate and the sowing of wild white clover are the chief remedies, and the Government's Land Fertility Scheme should stimulate the efforts already being made in these directions. Grassland management, and its counterpart, grass conservation, were the subjects of a group of papers in which the different methods of making hay, silage and dried grass were discussed, from both the nutritive and economic aspects. Questions affecting the arable farmer also received attention, and alternate husbandry, on both light and heavy land, was advocated as being valuable for the increase of productivity, profit and employment, and for the control of animal disease and the promotion of national defence. Problems connected with plant disease were represented in a paper on soil conditions and the control of foot-rot in cereals, and the Conference concluded with a discussion on the ever-recurrent question of weed control.

New Varieties of Spring Oats

PARTICULARS of two new varieties of spring oats that will be available for distribution for sowing this coming spring are given in Leaflet Series S. No. 4 (price 1*s*.) issued by the Welsh Plant Breeding Station, Aberystwyth, and farmers, co-operative societies and merchants desiring seed should make immediate application to the Station for supplies. Oats are grown over a wide range of soil and climate, and in the breeding work at Aberystwyth special attention is paid to the production of strains able to resist lodging and suitable to soils of varying productive capacity. The two new varieties, *S*. 84 and *S*. 175, are intended for soils of high and medium productive capacity respectively. For poor soils, the Ceirch

Llwyd Cwta (*S.* 171) is the more suitable variety, and useful information gained from practical experience in its cultivation during the previous season is to be found in the leaflet. Farmers growing the Aberystwyth strains are particularly requested to inform the Plant Breeding Station of the behaviour of the varieties in question, as such reports are of great value to those engaged on the selection work.

Conservation of Natural Resources

IN the United States, strenuous efforts are being made by the Government, through its Forest Service, National Park Service, Soil Conservation Service, Tennessee Valley Authority and other agencies to remedy the disastrous effects of years of neglect and exploitation. Many voluntary organizations cooperate. In "Conservation in the Education Program" (*Bulletin* No. 4 of 1937), the Commissioner of Education presents an account of the progress made in introducing into school curricula instruction designed to awaken an appreciation of the importance to the community of conservation of natural resources and the duty of the individual citizen in relation thereto. Such instruction is conveyed in general in connexion with regularly established school subjects such as nature-study, elementary science, the social sciences, particularly geography; but in at least one State "Protection and Conservation of Life, Property and Natural Resources" is one of a number of social functions selected as bases for organizing instruction according to the theory that things should be learnt in relation to the ways in which they will be used. In addition to outlining existing practices, the bulletin contains a detailed prospectus prepared in the Curriculum Construction Laboratory of Teachers College, Columbia University, of a course of instruction on the theme "How is Man trying to Conserve his Natural Resources".

The History of Science

WE have received vol. 3, part 1, of *Osiris*, the journal devoted to the history of science and edited by G. Sarton. This part is dedicated to Prof. E. O. von Lippmann, a biographical notice (with portrait) and a bibliography being contributed by J. R. Partington. Several of the articles deal with the history of mathematics and astronomy; there is also one on Sir Charles Blagden by F. H. Getman and one on Leeuwenhoek by A. W. Meyer, and L. B. Simpson contributes an account of the medicine of the Conquistadores based on a sixteenth century manuscript. The mathematical papers deal with linear and quadratic equations (Kloyda), the calculus of variations (Carathéodory), and the graphical representation of statistical data (Funkhouser). Other interesting papers make up a noteworthy issue.

Announcements

SIR JOHN ANDERSON, the National Government candidate, has been elected Member of Parliament in the Scottish Universities seat which became vacant on the death of Mr. Ramsay MacDonald.

THE Kelvin Medal Award Committee, on which are represented eight of the most important engineering institutions, has awarded the Kelvin Medal for 1938 to Sir J. J. Thomson, Master of Trinity College, Cambridge, in recognition of the eminent services he has rendered to engineering science. The presentation will be made by Lord Rayleigh at the Institution of Civil Engineers on May 3.

THE first award of the James Alfred Ewing Medal of the Institution of Civil Engineers has been made to Mr. C. S. Franklin, research expert, formerly chief of the Independent Research Department, of the Marconi Company. Mr. Franklin is known chiefly for his researches in connexion with the Marconi beam system. The Bayliss Prize of the Institution has been awarded to Mr. R. Kerridge.

THE following have been elected honorary members of the Institution of Civil Engineers: H.M. the King of the Belgians; H.R.H. the Crown Prince of Sweden; Sir Robert Elliott-Cooper, senior past-president of the Institution; and Sir Frank Smith, secretary of the Department of Scientific and Industrial Research.

SIR ALBERT SEWARD, formerly professor of botany in the University of Cambridge, has recently been elected a trustee of the British Museum.

PROF. E. S. Goodrich, Linacre professor of zoology and comparative anatomy in the University of Oxford, has been elected a member of the Section of Zoology of the Royal Swedish Academy of Science, Stockholm.

THE twenty-ninth Congress of the German Radiological Society will be held on July 4–7 at Munich under the presidency of Dr. G. A. Weltz. Further information can be obtained from Prof. Karl Frik, Bruckerallee 22, Berlin.

THE fifth International Congress of Cell Research will be held at Zurich on August 7–13, when the following subjects will be discussed: epithelium in cultures and in the organism, structure of chromosomes, mechanism of mitosis, cancer cell and normal cell, experimental cell investigation, and investigation of viruses. Further information can be obtained from Das Anatomische Institut, Plattenstrasse 9, Zurich 7.

THE annual Malaria Control Course for Laymen (engineers, planters, etc.) will be held at the Ross Institute of Tropical Hygiene commencing on June 27, 1938. The course will be under Sir Malcolm Watson, director of the Institute. It is designed for planters and mining engineers, but it will be of interest to all (including missionaries) who are proceeding to the tropics. Further information can be obtained from the Organizing Secretary, Ross Institute of Tropical Hygiene, Keppel Street (Gower Street), London, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

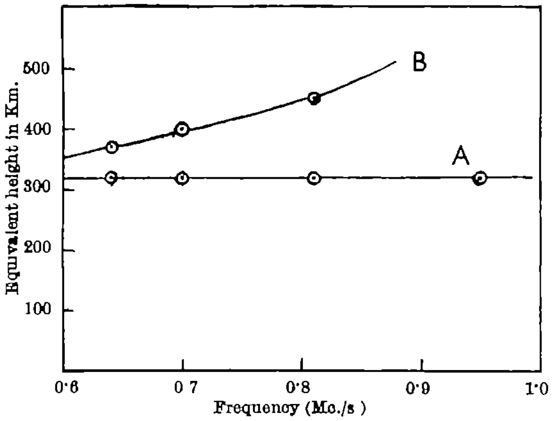
NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 417.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Magnetic Double Refraction of Medium Radio Waves in the Ionosphere

IN 1935, two of us[1] reported the results of experiments in which pulses were reflected from the ionosphere using a frequency less than the magneto-ionic gyro-frequency and in which the polarization of the echoes was determined by means of a "circularly polarized" receiving aerial. We found doubled echoes from region *F* on frequencies below about 1·0 Mc./s. and we showed that the echo of shorter delay had left-handed polarization and that of greater delay was right-handed. We therefore interpreted the two echoes as magneto-ionic components, and this interpretation was supported by observations of the change over of the reflection from region *F* to region *E*.

In further experiments of the type then reported, we have since investigated the way in which the echo doubling varies with frequency and have found that the separation between the two components increases as the frequency is increased as shown in the accompanying graph, which exhibits the results of measurements made at 0030 on December 14, 1935. We found that the right-handed echo *B* became weaker as the gyromagnetic frequency was approached, and we could not follow it above a frequency of about 0·9 Mc./s.



In a recent issue of NATURE, Martyn and Munro[2], who have conducted their experiments in the southern hemisphere, produced a graph very similar to that shown above, but have given quite a different interpretation of it. Since, however, in considering the results shown by our graph, we have now arrived at a more complete explanation on the lines of that previously given, it may be of interest to contrast the two interpretations.

Our own reading of the results exhibited in the accompanying graph is very simple. We consider that the curve *A* refers to the ordinary and *B* to the extraordinary ray echoes. Since we are dealing with a frequency *f*, which is less than the magnetic gyro-frequency f_H, the ordinary ray is reflected at a level in Region *F* where the electron concentration *N* is given by

$$N = \frac{\pi m}{e^2} f^2; \qquad (1)$$

while the extraordinary ray is reflected where *N* is greater, that is to say where

$$N = \frac{\pi m}{e^2} (f^2 + f f_H). \qquad (2)$$

Bajpai and Mathur[3] have shown that, for extraordinary waves of the frequency range we are considering, the group velocity is relatively low over most of their track in the ionized medium, so that these waves are delayed in time behind the ordinary waves. Delay occurs as a result of transmission both through regions E_1 and E_2 and through such part of region *F* as lies below the reflection level. This explanation agrees with the observed polarization of the waves. For frequencies approaching the gyro-frequency the absorption of the extraordinary wave echo is very considerable. This explains why it cannot be followed beyond about 0·9 Mc./sec.

The agreement of experiment and theory in the case of our experiments raises a difficulty in connexion with the Australian experiments, where the results to be explained are similar but are given a different interpretation. Martyn and Munro, for example, consider that both traces in their figure refer to ordinary waves, though no experimental check of similar polarization is mentioned. They accept, as we do, that the curve *A* represents the ordinary ray echo which is reflected at the level conditioned by equation (1); but they consider that curve *B* represents an echo due to waves which have penetrated the 'over-dense' stratum which lies between that level and a higher level where the ordinary ray refractive index becomes infinite. The value of *N* at this higher level is given by[4]

$$N = \frac{\pi m}{e^2} f^2 \left(\frac{f_H^2 - f^2}{f_H^2 \cos^2 \theta - f^2} \right). \qquad (3)$$

(There appear to be slips in the formula given by Martyn and Munro). Now it is easy to show that this interpretation requires that, when *f* approaches $f_H \cos\theta$, the waves should 'leak' through a 'barrier' of approximately 100 km. or about 400 vacuum wave-lengths. The difficulty of an explanation along these lines need not be elaborated beyond this point.

To settle the matter an examination of the polarization of the echoes obtained in Australia is needed. If both components are found to be of the same polarization, the explanation given by Martyn and

Munro is acceptable. If, on the other hand, the two echo-components are observed, as in England, to be of opposite polarization, the explanation of the phenomenon given by Martyn and Munro must be abandoned together with the two further deductions they have made from it.

Mean Free Path of Protons in the Universe

IT is known that on different occasions and in different forms a dimensionless constant of the order of between 10^{39} and 10^{40} recurs in physics—the variety being due to the fact that two other dimensionless combinations (hc/e^2 and m_P/m_e) are *comparatively* small and, besides, are of the *same* order (10^3). Some of us believe that the *large* constant is the square root of the number of mass-units (protons and neutrons) in the world (N). I propose to name 'Eddington's relation' the relationship between universal constants which springs from this assumption. For it is essentially *one* and we need a name for it, in order to be able to say, this is essentially Eddington's relation, when we are presented with a disguised form of it.

Moreover, it is known that, from that assumption, if Einstein's relation between mean mass density and curvature is admitted, reasonable values result for the radius (R) of the universe and its mean density (ρ); following Eddington: $N = 1{\cdot}57 \times 10^{79}$, $R = 1{\cdot}23 \times 10^{27}$ cm., $\rho = 3{\cdot}32 \times 10^{-27}$ gm./cm.^{3}).

An interesting form of Eddington's relation occurred to me recently. The mean distance between the closely packed mass-units in the nuclei[1] is $\delta = 3 \times 10^{-13}$ cm. It is seen that

$$\frac{R}{\delta} = \frac{1{\cdot}23 \times 10^{27}}{3 \times 10^{-13}} = 0{\cdot}4 \times 10^{40} \sim \sqrt{N} \text{ very nearly.} \qquad (1)$$

Now let us call it an 'encounter', when two mass-units approach each other within the distance δ; and let us calculate the average number of encounters (n) along a great circle, assuming that all the units are free and form a gas: then

$$n = \frac{2\pi R \,.\, \pi\delta^2}{2\pi^2 R^3} N = \frac{\delta^2}{R^2} N \sim 1. \qquad (2)$$

Thus, with uniform distribution, the mean free path would equal the world's circumference. In other words, the number of protons and neutrons would be just on the border-line of making the universe 'opaque' for a radiation to which each of them presented an absorbing cross-section of $\pi\delta^2$. Or again, the sum of the cross-sections of the particles is roughly of the same order (one sixteenth) as the cross-section of the universe.

There ought to be something essential in these very simple statements—unless Eddington's idea that the mass-unit is connected with the radius, R, is entirely deceptive. For, of course, δ *must* be connected with the mass-unit, since it is so very near to

$$\frac{h}{m_P c} = 1{\cdot}32 \times 10^{-13} \text{ cm.}$$

It ought, by the way, to be remembered that, in adopting Eddington's numbers, we already tacitly admit that the luminous masses concentrated in the nebulæ constitute but a small fraction, about one thousandth, of the mass of the universe.

Neon and Argon in the Earth's Crust

IN the atmosphere, atoms of argon are some 520 times as abundant as atoms of neon. Russell and Menzel[1] have emphasized that in celestial sources neon is much the more abundant. This they explain by the hypothesis that the atmosphere has lost most of its neon, which it could only do at the time of its birth, when the temperature was presumably very high.

From this point of view, it is of interest to examine the earth's crust for argon and neon. I find, in fact, that granite contains these gases, the quantity being of the order of 10^{-6} c.c. neon, and 4×10^{-5} c.c. argon per gram of granite. The argon atoms are thus only some 40 times as abundant as the neon, instead of 520 times as in the atmosphere. These figures are derived from the examination of four samples of granite from different localities. The gases are liberated by decomposing the granite with fused caustic potash. The experiments are difficult because of the risk of atmospheric contamination, but it is believed that this source of error has been avoided. That the ratio neon/argon is greater than for the atmosphere is readily verified. The excess of helium present in the crude rare gases must first be got rid of, and I have done this by allowing it to diffuse out through red-hot silica. The argon spectrum is then dominant, but the yellow line of neon is conspicuous in it, whereas this line is not visible in the neon-argon mixture obtained from the atmosphere. The relative richness in neon is thus verified at a single *coup d'oeil*, and the spectroscopic result can be made quantitative by comparison with made-up mixtures of argon and neon. This gives a check on the volume measurements made on the separated gases.

The present results seem favourable to the view that there has at some time been a loss of neon from the atmosphere. They will be published in detail later. The further question of the ratio of argon to nitrogen in rocks is under examination.

Electron-Multiplier for Measuring Ionization Currents

THE letter from Prof. Z. Bay[1] gave details of the application of electron-multipliers to the measurement of photons and electrons emitted *in vacuo*. Experiments on similar lines have been carried out in this laboratory with the object of using electron-multipliers for measuring small ionization currents due to any type of radiation.

The saturation current in an ionization chamber was arranged to control the potential and hence the number of electrons emitted from the illuminated photo-electric cathode of the electron-multiplier. The emitted photo-electrons were then accelerated on to a series of secondary electron emitting stages consisting of fine mesh grids, sensitized for maximum secondary electron emission, and arranged as parallel disks inside a metal focusing cylinder. The initial photo-electron current was thus amplified by secondary electron emission and the output current measured on an ordinary microammeter.

In this manner currents of the order of 10^{-12} amp. have been amplified to currents of between 10^{-6} and 10^{-3} amp., while it is possible to detect currents of the order of 10^{-14} amp. Attempts are now being made to measure even smaller currents. The main difficulty to be overcome is, as mentioned by Prof. Bay, a reduction of the thermionic emission of electrons from the multiplying grids. As he has shown, this can be done by cooling the electron multiplier down to temperatures in the region of 120°–150° K. This, however, is considered rather an unpractical procedure for general use. Experiments are now being made with secondary electron emitting surfaces having high work functions and correspondingly low thermal electron emission coefficients.

The advantages of this system of amplification is its general stability, it being comparatively insensitive to changes in the working potentials, making the operation from A.C. mains quite practical. Also, it is unnecessary to use delicate galvanometers, very high resistances, or sensitive balancing circuits, as the output current is large enough to be measured on a microammeter or milliammeter.

On behalf of the governing body, I wish to thank Messrs. Baird Television, Ltd. for their willing co-operation in these experiments. A detailed report of this work is to be published at a later date.

Significance of Gravity Anomalies in Relation to the Viscosity of the Asthenosphere

SOME time ago I published an estimate of the mean viscosity of the earth's silicate mantle on the basis of the rate of post-Glacial uplift of the Fennoscandian region[1]. It has been suggested recently[2] that if that estimate is correct, areas of large negative gravity anomalies, such as that in the Gangetic trough in India, should be rising at an observable rate. It is the purpose of this communication to examine this question briefly.

In the paper referred to, it was shown that at the centre of a radially symmetrical depression in the surface of a highly viscous fluid, the displacement of the surface, $\zeta\,(0)$, and the vertical velocity at the surface, $V\,(0)$, are connected by the relation

$$\zeta\,(0) = \frac{2\sqrt{\pi}\,\eta\,b}{\rho\,g}\,V\,(0), \qquad (1)$$

where g is the acceleration of gravity, η and ρ are respectively the coefficient of viscosity and the density of the fluid, and b is a quantity determined by fitting the surface velocity as a function of the radius, r, to a function of the form

$$V\,(r) = V\,(0)\,e^{-b^2r^2}. \qquad (2)$$

In other words, b may be regarded as the reciprocal of the effective radius of the depression. The quantities $\zeta\,(0)$, $V\,(0)$, and b were determined from data for the post-Glacial uplift of the Fennoscandian region given by Nansen[3], and the kinematic viscosity, η/ρ, was found from equation (1) to be of the order of 3×10^{21} cm.^{2} sec.$^{-1}$.

The Gangetic area of negative anomalies has the form of a long strip, hence instead of equation (1) it would be better in this case to use the equivalent expression for a long trough-like depression. This is

$$\zeta\,(0) = \frac{4\,\eta\,b}{\sqrt{\pi}\,\rho\,g}\,V\,(0). \qquad (3)$$

Equation (3) may be applied directly to the present problem by noting that the depression of the surface is equivalent to a negative load $\sigma = \zeta\,\rho\,g$ dynes per square centimetre. We then have for the velocity at the centre of a loaded strip,

$$V\,(0) = \frac{\sqrt{\pi}\,\sigma\,(0)}{4\,\eta\,b} \qquad (4)$$

where b^{-1} is now one half the effective width of the strip.

The greatest distance between the lines of zero anomaly in a direction perpendicular to the axis of the belt is approximately 400 km.; b^{-1} is then somewhat less than 200 km., and, by analogy with the example worked out in the paper referred to above[1], it should be about 3/4 of this, or 150 km. The defect of load at the centre is of the order of 4×10^8 dynes per square centimetre. If we take $\eta = 10^{22}$, equation (4) gives a rate of uplift at the centre of 8·4 metres per century. This figure should be somewhat reduced since the actual distribution of the load can be better approximated by some distribution intermediate between the linear trough assumed in deriving (3) and the circular depression assumed in deriving (1). The other quantities being equal, the velocity for the circular load is 0·636 times the velocity for the linear load. Thus we should multiply our result by some factor between 0·636 and unity, say 0·9. The indicated rate of uplift will then be somewhere in the neighbourhood of 7·6 metres per century.

Results of repetition of earlier surveys have been interpreted[4] as indicating a rate of uplift varying from zero about fifty miles north of Calcutta to six feet per century in the neighbourhood of Benares. It has also been suggested that sudden changes of level have taken place in connexion with earthquakes, so that the average rate over a period of many centuries might be comparable with that derived above. However, both the levelling results and the changes of level associated with the Bihar earthquake of 1934 have been questioned[5], so that it may be advisable to consider what modifications of the theoretical discussions would be required in case it were demonstrated conclusively that the rate of uplift is of a smaller order of magnitude. Two possibilities are open. (1) The value taken for the coefficient of viscosity may be very much too small. But if that is true, then some mechanism other than viscous flow must be devised to account for the observed rate of uplift in Fennoscandia and the fact that the area which has undergone uplift in post-Glacial time coincides with the area which had formerly been covered by an ice cap. (2) The crust may be strong enough to support a load of the magnitude indicated so that viscous yielding at depth does not enter into the question at all. In the case of a load the span of which is many times the thickness of the crust, as it is in the case of a continental ice sheet, the crust itself might bend elastically while the weaker substratum was displaced by plastic flow. Thus it is not necessary to suppose that the load was great enough to cause stresses exceeding the strength of the crust; it would have to be great enough to exceed the strength at greater depths. On the other hand, a load the span of which is comparable with the thickness of the crust, such as we are dealing with here, could cause only a slight elastic deflection of the crust; hence appreciable plastic flow in the subtratum would take place only if the load were great enough to cause failure of the crust.

Jeffreys has shown[6] that if hydrostatic conditions are assumed below the crust, an uncompensated load implies a strength of the order of $2d/kh$, for a load having the form $d \cos kx$, where h is the thickness of the crust. This is $2dl/\pi h$ where l is one half the wavelength, that is, roughly the equivalent of b^{-1} in the present case. Our quantity $\sigma(0)$ should be identified with the total range of load, $2a$. The stress difference is then $\sigma(0)/\pi bh$. There is some uncertainty as to what value we should use for h in this expression. If we take it to be the Hayford depth of compensation, it is of the order of 100 km. On the other hand, it might conceivably be as small as the depth of the Mohorovičić discontinuity, which has a minimum depth of 25 km.[7] If we use the latter figure, we have a maximum stress difference of $7 \cdot 6 \times 10^8$ dynes per square centimetre. This is less than the strength of granite at the surface, and, considering the rapid increase of strength with pressure[8], it is far less than the strength which must prevail at depths of a few kilometres. It should not, therefore, be necessary to assume a viscosity greater than 10^{22} gm. cm.$^{-1}$ sec.$^{-1}$. In fact, if it should turn out that uplift actually is going on in the Gangetic trough, it would become a problem to explain why the crust should yield at all to stresses of this order.

Kepler, Newton and Bode

MR. J. MILLER's observation[1] that the orbits of the satellites of Saturn are distributed about the primary in a manner similar to that of the planets about the sun, leads one to suspect that Newton's law of gravitation is only a particular case of a more general law. Bode's law can no longer be regarded as fortuitous. Kepler's relation between planetary distances and periods may only apply at the distances given by Bode's law. If this is so, Newton's inverse square law only applies at those same distances—distances for which the actual law of force gives stable orbits.

It seems possible to have a law of force, other than that of the inverse square, which will give all three laws of Kepler, Newton and Bode for the stable orbits. If we take the force for a circular orbit as

$$P = \mu^2 \varphi(\mu),$$

it can be shown that for a stable orbit

$$\frac{\mu \varphi^1(\mu)}{\varphi(\mu)}$$

must lie between 0 and 1. But

$$\varphi(\mu) = \frac{4\pi^2}{\mu^3} \cdot \frac{1}{T^2},$$

where T is the period. Hence

$$\frac{\mu \varphi^1(\mu)}{\varphi(\mu)} = -\mu\left(\frac{2}{T} \cdot \frac{dT}{d\mu} + \frac{3}{\mu}\right).$$

For this to be 1,

$$\frac{dT}{d\mu} = -\frac{2T}{\mu};$$

and for it to be 0,

$$\frac{dT}{d\mu} = -\frac{3T}{2\mu}.$$

These expressions correspond to the limits of the band of stability between which an orbit can lie. Since the second expression agrees with Kepler's observation, all the planets occupy orbits on the outer edges of the bands of stability. In these positions, $\varphi(\mu) =$ constant, that is, Newton's law. But this is not the only value for $\varphi(\mu)$ which will give Kepler's law for the planets. There may be many such values. For example, if

$$\varphi(\mu) = \cos^2\left(\frac{1}{\mu}\right),$$

then

$$\frac{\mu \varphi^1(\mu)}{\varphi(\mu)} = \frac{2}{\mu} \tan\left(\frac{1}{\mu}\right),$$

which is 0 whenever $\frac{1}{\mu} = r = n\pi$.

If a shape for $\varphi(\mu)$ can be found which will make $\frac{\mu\,\varphi^1(\mu)}{\varphi(\mu)} = 0$ when $\frac{1}{\mu} = 3 \times 2^{(n-2)} + 4$, n being 1, 2, 3, etc., then a law of force giving Kepler, Newton and Bode will have been discovered.

Interatomic Distances of $FCCl_3$ and $FCBr_3$

IN some early work we measured the interatomic distances of different methane and silane halides by means of the electron diffraction method. We wish to give here distances between atoms of $FCCl_3$ and $FCBr_3$ measured by the same method. These substances have been prepared and purified by Prof. F. Swarts. We are much indebted to him for giving us the opportunity of measuring these substances.

The values obtained (in A.) are:

$FCCl_3$: Cl–Cl = 2·94 ± 0·03; Cl–F = 2·56 ± 0·04; C–F = 1·44 ± 0·04; C–Cl = 1·76 ± 0·02:

$FCBr_3$: Br–Br = 3·20 ± 0·03; Br–F = 2·70 ± 0·02; C–F = 1·44 ± 0·06; C–Br = 1·91 ± 0·04.

One of these substances, namely, $FCCl_3$, has already been measured by Brockway[1]. His values (in A.) are :

$Cl–Cl = 2·91 \pm 0·03$; $Cl–F = 2·56 \pm 0·04$; $F–C = 1·40 \pm 0·04$; $C–Cl = 1·76 \pm 0·02$.

Thus they are very close to those found by us. The results show : (1) that the distance C–F remains very nearly constant in both compounds ; (2) that the distance C–Cl shows the same value in all compounds containing $C–Cl_3$ with the exception of $C–Cl_4$; the same conclusion is valid for C–Br ; (3) going from $FCCl_3$ to $FCBr_3$, the pyramid CX_3 expands with a factor 1·088. A factor 1·075 may be used in passing from $HCCl_3$ to $HCBr_3$, and also in passing from $HSiCl_3$ to $HSiBr_3$ [2].

A more extended discussion of these data will be published elsewhere.

A New Type of Structure in the α-Copper-Zinc Alloys

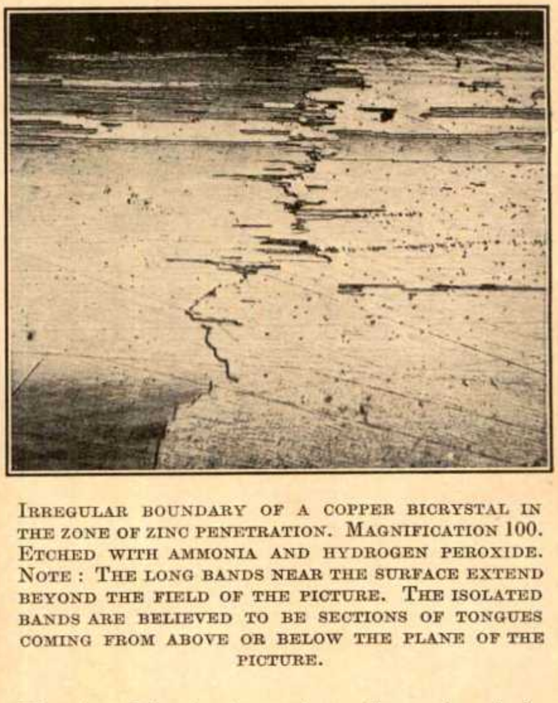
CERTAIN banded structures seen in cast α-brass after annealing have been identified by several investigators as true twins. Recently we have made an observation which suggests that there may exist structures that appear to be twins, but that are not twins. The observations were made upon two large cast copper crystals joined at a natural boundary which lay almost perpendicular to the external surface of the sample. Into this bicrystal, zinc was diffused by exposing it to the vapour from α-brass turnings at a temperature of 775° C. The system was enclosed in an evacuated silica tube. Zinc penetrated to a uniform depth over the entire surface of the specimen and gave a layer of perhaps half a millimetre of yellow brass.

Upon examination of a cross-section of the bicrystal, it was found that the grain boundary of the copper crystals had been disturbed within the zone of zinc penetration. In some regions along the original boundary, local recrystallization had occurred ; but in others a peculiar type of grain growth appeared with the complete absence of new crystal formation. In the latter case the two grains were seen to have grown into each other in long parallel finger-like bands, greatly resembling twins (see accompanying photomicrograph), and leaving a much lengthened boundary running back and forth in zig-zags nearly parallel to the external surface of the sample. The breadth of the fingers thus formed was irregular, but in general was seen to be least near the surface of the sample and greatest at the limit of the yellow brass zone, beyond which the original boundary remained undisturbed.

It was at first surmised that this remarkable structure might have resulted from the highly improbable occurrence of the two grains of the bicrystal in a mutually twinned relationship, with their orientations such that a twinning plane lay parallel to the external surface. This situation could conceivably permit the two crystals to grow into one another in long bands by the simple operation of twinning. By means of an X-ray determination of the orientations of the two crystals, it was shown that they did not bear a mutually twinned relationship. In fact, the nearest approach of octahedral planes (twinning planes) between the two crystals was eight degrees. The bands, therefore, are not twins, but simple projections of one crystal into the other.

In all probability this displacement of the grain boundary can be traced to a periodic crystal growth induced by the strains set up within successive layers of the copper by the expansion required to accommodate the inwardly diffusing zinc. Presumably, the direction of growth is a matter of chance in each successive step, for the projections are distributed about equally on the two sides of the original boundary. Upon the basis of this hypothesis, it is to be expected that the bands would be narrowest near the surface of the sample, because in that region the concentration gradient of the zinc would be the steepest.

To the foregoing observations it may be added that in the present studies recrystallization and grain growth resulting from diffusion have been observed adjacent to flat surfaces and at sharp corners, but not in samples having convex surfaces.



IRREGULAR BOUNDARY OF A COPPER BICRYSTAL IN THE ZONE OF ZINC PENETRATION. MAGNIFICATION 100. ETCHED WITH AMMONIA AND HYDROGEN PEROXIDE. NOTE : THE LONG BANDS NEAR THE SURFACE EXTEND BEYOND THE FIELD OF THE PICTURE. THE ISOLATED BANDS ARE BELIEVED TO BE SECTIONS OF TONGUES COMING FROM ABOVE OR BELOW THE PLANE OF THE PICTURE.

The banded structures have been found in a number of different samples. Whether or not its occurrence requires the existence of special orientation relationships between the participating crystals could not be determined from the few data at hand. Although it seems likely that the diffusion occurring during the homogenization of cast α-brass could establish conditions similar to those existing in the bicrystals, this structure has not yet been definitely identified by us in a polycrystalline brass. Some of the bands seen in technical homogenized α-brass may well be this structure !

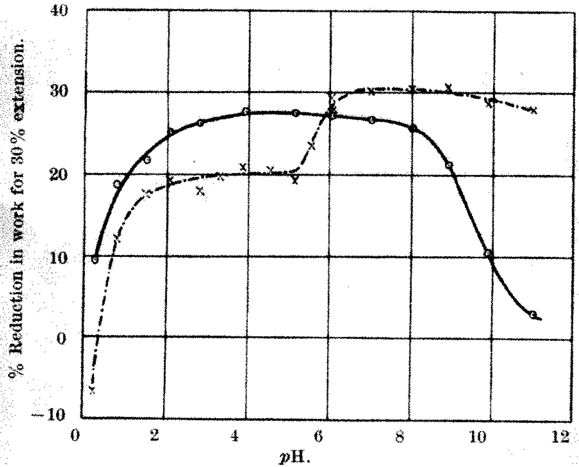
Constitution of the Keratin Molecule

DURING the past few years, much evidence has been accumulated in support of the view that the free acid and basic side-chains of wool are equivalent and form salt linkages between the peptide chains[1]. Although further proof of the salt linkage hypothesis may seem to be redundant in view of recent determinations of the amounts of aspartic and glutamic acids in wool[2], a proof based on the properties of deaminated fibres is essential to refute the erroneous conclusions drawn by Sookne and Harris[3] from a study of deaminated wool.

The resistance to extension of keratin fibres in acid and alkaline solutions is less than in water because of the breakdown of salt- and, above *p*H 10, sulphur-linkages between the peptide chains. A curve illustrating the reduction in the resistance of human hair fibres to extension in buffer solutions of varying *p*H, as compared with distilled water at *p*H 5·5, is given in the accompanying graph.



RESISTANCE OF HUMAN HAIR TO EXTENSION IN VARIOUS BUFFER SOLUTIONS; ⊙—⊙—⊙, UNTREATED; X—·—X—·—X·, DEAMINATED.

The undamaged root ends of human hair fibres were used in preference to wool because of the greater uniformity of the fibres, but the form of the curve, as well as the extent of the *p*H-stability region, are in conformity with the salt linkage hypothesis. When human hair fibres are deaminated, however, their resistance to extension should be sensibly independent of the acidity of the solution below *p*H 5, because there are then no salt linkages to be broken by acid. As the curve shows, within small limits, such is the case for single fibres deaminated by two treatments of 24 hours each in 40 c.c. of the van Slyke reagent at 22·2° C. in absence of air.

In terms of the salt linkage hypothesis, too, removal of the basic side-chains by deamination should free a corresponding number of acid side-chains for combination with alkali in the neighbourhood of *p*H 6. The fibre swelling thereby induced should reduce the resistance to extension, although to a relatively small extent because the reduction is due solely to swelling and not to breakdown of salt linkages. As shown in the graph, the resistance to extension of deaminated fibres decreases sharply between *p*H 5 and 7, in agreement with theory. Above *p*H 7, the resistance to extension is sensibly independent of *p*H until the sulphur bonds are attacked by alkali.

Thus the elastic properties of deaminated fibres are in strict agreement with the salt linkage hypothesis. The corresponding titration curve for deaminated human hair is now being determined.

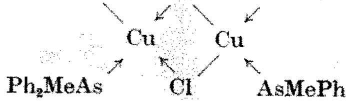
A Novel Type of Isomerism in a Co-ordination Compound of Copper

IF a warm alcoholic solution of cupric chloride is treated with diphenyl methyl arsine and allowed to stand overnight, two crystalline species (brown and blue) of identical composition $(Cu_2(Ph_2MeAs)_3Cl_3)$ are deposited. The separation of these two substances has already been described[1]. At that time the evidence put forward was insufficient to show whether the two compounds were really isomeric or not. Recently, however, it has been found that the two compounds are appreciably soluble in nitro-benzene, in which solvent the molecular weights of the two are of the same order (brown 878, blue 786). One form is therefore not a polymer of the other. Furthermore, these values, although somewhat lower than the theoretical (986), support the view that each form is binuclear.

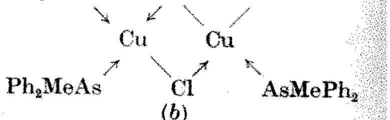
The brown form dissolves in thoroughly dried nitrobenzene to give a brown solution. This solution is quite stable at low temperatures and will deposit the brown crystals when cooled sufficiently; but if it is heated to 150° (or more) the brown colour will, during the course of half an hour, change to a greenish blue. The greenish blue solution will deposit crystals of the blue form on cooling. There is nothing to indicate that one form is a hydrate of the other. The fact that solutions of each form in the same solvent are differently coloured rules out the possibility of dimorphism. In confirmation of this it may be noted that the two forms behave differently towards ammonia and pyridine.

All the evidence available points to the conclusion that the two forms are isomers. Of the two, the brown form is the more stable. Even in the dry state the blue form has been found to revert to the brown over a period of several months. As would be expected, the transition of the blue to the brown form is more rapid in nitrobenzene solution. At room temperature, both forms are stable insofar as they show no tendency to lose the arsine even on long standing.

In order to account for the existence of two isomeric forms, the following structures attributing tetrahedral co-ordination to Cu^I and square co-ordination to Cu^{II} are suggested:

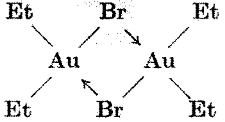


(*a*)

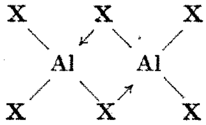


(*b*)

There is ample evidence from crystal structure analyses[2] that, in the bivalent state, copper is square co-ordinated, a finding which is also in accord with the results of Pauling's wave mechanical treatment of the question of bond orientation[3]. In both (*a*) and (*b*) therefore, all four bonds to Cu^{II} lie in the plane of the paper. On the other hand, univalent copper forms tetrahedral electron pair bonds as in Cu_2O, $K_3[Cu(CN)_4]$ and CuCl[4]. Thus the two bonds to Cu^{I} on the left of (*a*) and (*b*) lie one above and the other below the plane of the paper. If both Cu^{I} and Cu^{II} were tetrahedrally co-ordinated, there would be no possibility of isomerism, but with Cu^{II} square co-ordinated two isomers are possible as indicated in the proposed structures. Other instances in which two halogen atoms are considered as forming bridges between metallic atoms could be cited[5]. For example, diethylmonobromogold is believed[6] to have the following structure:



This is supported by crystal structure data for the compound. Further physical evidence that halogen atoms may function in this way is to be found in the results of electron diffraction investigations of the vapours of aluminium halides[7]. These indicate that the molecules have the structure:



(X = halogen).

So far, a study of the reactions of the isomers with pyridine, ethylenediamine and ammonia has provided no decisive evidence in favour of the structures. Work along these lines is, however, being continued and it is hoped later to test the structures by a physical method.

Electrophoretic Behaviour in Nucleic Acid-Protein Mixtures

SOME noteworthy observations have been made in the course of an investigation of the electrophoretic properties of pure thymonucleic acid and mixtures of it with electrophoretically purified seralbumin. The technique employed has been described by Tiselius[1]. The results as regards the electrical mobilities and the mutual interactions between the nucleic acid and the protein will be presented elsewhere in the near future. Here it may be of interest to point out the remarkable behaviour of the serum pigment.

The seralbumin as usual contained a yellowish pigment (bilirubin, etc.) which could not be separated from protein even after repeated electrophoresis at *p*H values ranging from 4·12 to 8·00 (cf. also Bennhold[2] and Pedersen and Waldenström[3]). When, however, the albumin was electrophorized in the presence of nucleic acid, it was observed that the pigment changed 'carrier' and migrated with the nucleic acid. On the negative side, a completely *colourless* albumin remained behind.

An experiment with urobilin showed that this substance alone had a very slight mobility (*p*H 4·9), but when mixed with nucleic acid it migrated at the same high velocity as the latter.

Recently a similar 'carrier shift' has been observed by Ågren and Hammarsten[4], who were able to purify carboxypolypeptidase preparations from tryptic activity by means of electrophoresis in the presence of protamin.

A related phenomenon of pigment displacement has been emphasized by Bennhold[2] in discussions on the *Vehikel Funktion* of the plasma proteins.

Blood Group Inheritance

J. Ffoulkes Edwards and Dr. I. M. H. Etherington[1] have continued the discussion initiated by R. Elsdon Dew[2], who quoted J. S. de Goldfiem's[3] figures for the blood group distribution among the French Soussoux. Of these, 89 per cent belong to Group *AB*, and Edwards and Etherington explain this obvious anomaly by re-advancing their quadruple allelomorph theory of group inheritance. This appears to be entirely unnecessary, nor does their theory fit the figures observed elsewhere, and before enlarging on this hypothesis, it seems pertinent to inquire whether there really are 89 per cent of the population in this group. In the original investigation, Vincent's whole blood technique of grouping was used, which is notorious for its high percentage of false results due to pseudo-agglutination. It would appear far more probable that the error lies in the technique adopted—either in the failure to differentiate between pseudo- and true iso-agglutination, or in a bacterial pan-agglutination from infection of the test sera—than that Bernstein's triple allelomorph theory of inheritance, which fits so well all the known figures, should be at fault.

Separation of Flavin and Phosphorylated Flavin

Greene and Black[1] have found that phenol, the cresols, aniline and benzyl-alcohol are suitable for the extraction of free flavin from water.

Using a solution of phosphorylated flavin (purified liver extract), I found that phenol also rapidly took up phosphorylated flavin from water.

It appeared, however, that practically no phosphorylated flavin was extracted by benzyl-alcohol when a solution of phosphorylated flavin in water was shaken with an equal volume of benzyl-alcohol (*p*H values from 5 to 7·4 and salt concentrations from 0·5 to 4·5 per cent NaCl). Under these conditions one benzyl-alcohol extraction removed 76–79 per cent of free flavin from water. Other aromatic alcohols (phenylethanol, phenylpropanol and phenylethylmethylethylcarbinol also permitted a separation.

Details and applications by these methods of separation (for example, urinary excretion) will be published elsewhere.

Biological Effects of Deuteron-Deuteron-Neutrons

THE biological effects of neutrons produced by a cyclotron have been reported by Lawrence and others. However, neutrons generated by a cyclotron, using beryllium targets, are accompanied by a great deal of γ-radiation, and the effect cannot be attributed entirely to neutrons. The purest neutrons ever known are D-D-neutrons, which are produced by bombarding 'heavy' ice (D_2O) with deuterons accelerated by high voltage, that is, by the reaction of

$$ {}_1D^2 + {}_1D^2 \rightarrow {}_2He^3 + {}_0n^1. $$

Since June 1937, through the kindness of the Nishikawa Laboratory of the Institute of Physical and Chemical Research, Tokyo, I have been examining the biological effects on young rats of irradiating them with D-D-neutrons. As the maximum range of recoil protons generated by neutrons is great, we have made a special ionization chamber with aluminium walls 2 mm. thick, lined with a 0·2 mm. layer of paraffin, and filled with methane gas, in order to measure the total ionization. By comparison with a known quantity of γ-rays from radium, we measured the intensity of neutrons, and the result showed that, at 250 kv. and 20 μ A., the ionization at 3·5 cm. from the source was equal to 1·3 r/hour. The following observations were made by irradiating young rats of about 20 gm. body weight with 10–30 r of D-D-neutrons.

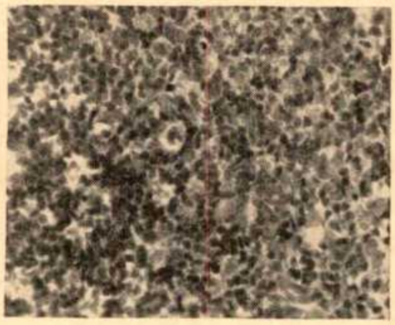

Fig. 1.
IRRADIATED THYMUS.

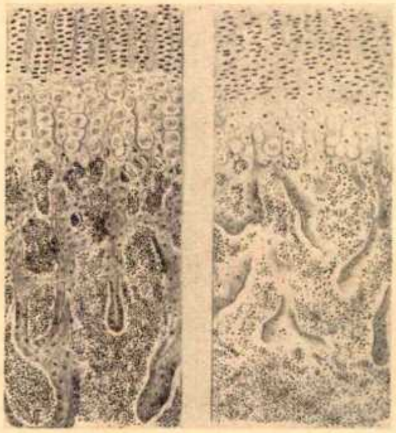

Fig. 2.
BONE AND BONE MARROW BEFORE (LEFT) AND AFTER (RIGHT) IRRADIATION.

The rats, irradiated with 30 r, did not increase in weight, and died in 5–10 days. With 26 r, rats showed no increase in weight for more than two weeks. About one half the amount of neutrons abovementioned allowed the rats to increase slightly in weight after a week, but they were still very poor in growth, even after four weeks. After irradiation with 12 r, the total leucocytes decreased to about one half, that is, 3,600–4,800. This state continued with or without further irradiation. The most conspicuous was the decrease of lymphocytes, which decreased from 70–80 per cent to 20–40 per cent, and their absolute number was so low as 1000 or less after two weeks. Neutrophil leucocytes, on the other hand, increased from 12–20 per cent to 40–77 per cent, and their absolute number also increased. Monocytes increased for a time, but afterward decreased, and eosinophil leucocytes gradually decreased and finally disappeared. Red cells and hæmoglobin gradually decreased, nucleated red cells appearing in the circulating blood in many cases.

At necropsy, anæmia of every organ was marked. Spleen, testis, ovary, thymus, bone, etc., were especially decreased considerably in size. Microscopically, the lymph follicles of the spleen were found to be most quickly affected, where destruction or decrease of lymphoid cells could be seen. Following this, the degeneration of megacaryocytes in pulp came about. Two weeks after exposure to 26–30 r, we found practically no lymphoid cells in the lymph follicles, reticulum cells remained withered in thread-like form, and infiltration of polymorphonuclear leucocytes appeared. Megacaryocytes in pulp having almost gone, many small round myeloid cells with positive oxidase reaction appeared. There were also hæmosiderosis and erythrophagia. Four weeks after, many megacaryocytes appeared, also many myeloid cells, showing bloomy myeloid metaplasia, but the regeneration of lymph follicles was still unsatisfactory.

In the bone marrow, decrease of myeloid cells could be seen immediately after irradiation. Two weeks after the irradiation with about 30 r, bone marrow cells became very scarce, and blood vessels much enlarged. Most of the myeloid cells were very small, as seen in the pulp of spleen, and megacaryocytes, normoblastes, etc., were scarce. Four weeks after, various myeloid cells increased very much, and vigorous hæmatopoiesis was observed. The irradiated lymph nodes showed destruction or decrease of lymphocytes at an early stage, and two weeks after irradiation with 30 r, lymphocytes were entirely gone, and marked infiltration of polymorphonuclear leucocytes appeared. Four weeks after, islands of myeloid metaplasia came out, but lymphoid cells did not yet appear. In the thymus also degeneration and decrease of lymphocytes were conspicuous (Fig. 1). Epitheloid cells also degenerated and became fewer as a whole. Medulla was more affected than was cortex. As to the bone, we found in enchondral ossification at the epiphysis of the femur, four or five days after irradiation, degeneration and derangement in the cells of proliferating, hypertrophic and carcificating zones. Cartilaginous processes decreased in number and became thin. The injury to osteoblasts was still greater, and the growth of bone cells was very poor (Fig. 2); in consequence the greater part of the bone remained in the state of primary ossification. In the testis no spermatozoa were seen, our rats being immature, but spermatids, spermatocytes and spermatogonia were degenerated or decreased in number in most irradiated animals, Sertoli's cells and interstitial cells, however, showing no marked change.

As to other organs, the hypophysis showed degeneration chiefly in the eosinophil cells of the anterior lobe; pineal, for the most part, degeneration of epitheloid cells: adrenals, marked decrease of cortical fat, and degeneration in zona glomerulosa, where alone was seen lipoid deposits (Sudan III positive); liver, peripheral fatty degeneration in some cases; and kidney, irregular lipoid deposits (Sudan III positive) in the principal division of urinary tubule.

I wish to express my thanks to Prof. S. Nishikawa, Dr. H. Yamakawa and Dr. M. Miwa for their kind advice and interest in this work.

Points from Foregoing Letters

A GRAPH showing that the separation of the two components of the radio waves reflected from region *F* of the ionosphere increases with the frequency, is submitted by Prof. E. V. Appleton, Dr. F. T. Farmer and J. A. Ratcliffe. The new findings, the authors point out, agree with their view that the two components are differently polarized, but cannot be readily explained on the supposition of Martyn and Munro who, from their experiments in Australia, deduced that both components are normal, but one penetrates into an 'over-dense' stratum. The writers calculate that on this hypothesis the waves would have to 'leak' through a barrier of approximately 100 km. or about 400 vacuum wave-lengths—an unlikely occurrence.

Prof. E. Schrödinger proposes the name 'Eddington's constant' for the large dimensionless constant, of the order 10^{39} or 10^{40}, which recurs in physics and is believed by some to be the square root of the number of mass-units (protons and neutrons) in the universe. Assuming uniform distribution, Prof. Schrödinger calculates the mean free path of the particles to equal the circumference of the universe and the sum of their cross-sections to be about one sixteenth the cross-section of the universe.

Lord Rayleigh finds that granite contains neon and argon, the relative amount of the former being some 13 times as great as in the atmosphere. This affords some confirmation of the suggestion by Russell and Menzel that the atmosphere has lost most of the neon that it formerly contained.

An 'electron-multiplier' similar to that recently described by Prof. Z. Bay, has also been constructed by Dr. W. H. Rann, who states that it has enabled him to detect currents of the order of 10^{-14} amp. and to amplify currents of 10^{-12} amp. to 10^{-6} or 10^{-5} amp. so that they can be measured on a microammeter or milliammeter.

N. A. Haskell calculates that the land in the trough of the Ganges would rise at the rate of about 7·6 metres per century, owing to the 'negative gravity' effect, if the viscosity of the underlying 'asthenosphere' has a value agreeing with that deduced from the rate of post-Glacial uplift of the Finnish-Scandinavian region.

If the orbits of planets and of satellites about their primaries are specified by Bode's law, then, Prof. G. W. Todd suggests, the laws of Kepler and Newton are only special cases of a more general law of gravitation.

Prof. F. N. Rhines and A. M. Montgomery find that a banded microstructure produced at the junction of two copper crystals into which zinc vapour had diffused, though looking very much like twinning, is not in fact due to twin crystals, but seems to have arisen through the growth of long, parallel, fingerlike bands from one crystal into the other.

Curves showing the reduction in the resistance to extension of human hair fibres (normal and deaminated) in buffer solutions of different acidity and alkalinity are given by Dr. J. B. Speakman and E. Stott. The authors state that the observed behaviour supports the salt-linkage theory for the constitution of the keratin molecule.

The preparation of two crystalline addition compounds, one brown and the other blue, of cupric chloride and diphenyl methyl arsine ($Cu_2(Ph_2MeAs)_3Cl_3$) is described by D. P. Mellor, G. J. Burrows and B. S. Morris. The authors consider that these represent a novel type of isomerism.

E. Stenhagen and Dr. T. Teorell report that when thymonucleic acid is added to a solution of seralbumin containing a yellow pigment (bilirubin, etc.)—from which it cannot normally be separated—and an electric current is passed, the pigment changes its 'carrier' and migrates with the nucleic acid.

Benzyl alcohol may be used to separate flavin from phosphorylated flavin, according to A. Emmerie, since it extracts the flavin but not the phosphorylated compound, from aqueous solutions.

Research Items

Neolithic Settlements in Danubian Yugoslavia

RECENT archæological reconnaissance by the American Expedition to Yugoslavia in the Yugoslav portion of the lower Danubian Valley, that is, on the right bank from the Iron Gate to the mouth of the Timok, the left bank being Rumanian, has resulted in fresh data from a score of sites, of which five are extensive settlements with rich neolithic deposits. The investigation of these sites, situated in a region of which the prehistory is at present incompletely understood, has been described and the results analysed by Mr. Vladimir J. Fewkes (*Proc. Amer. Phil. Soc.*, 78, 2; 1978). Observation is facilitated by the fact that the settlements, being situated along the bank of the river, have suffered much from erosion, which has exposed vertical profiles of the deposits. Systematic excavation on an extended scale, however, is an urgent necessity. Recent reconnoitring has established fresh evidence of neolithic occupation consisting of deposits *in situ* revealing dwelling pits as well as floors, and secondarily placed material, both related and unrelated to the settlement deposits. Additional data of later periods, of Bronze Age, La Téne and Early Slávic date, have been found. The material of neolithic age is characteristic of the Danubian Valley at large, including the barbotine pottery, which is widely distributed in the Danubian region. This pottery provides material for comparison and chronological study. Locally it is associated with the initial occupation, to which belong the lowest deposits characterized by pit-dwellings only. These show no traces of posts, which occur only with the later remains of dwellings with packed floors and without sub-pits, where the characteristic pottery is no longer barbotine, but incised, fluted, burnished and hand-smoothed wares. The neolithic evidence is invariably clearly intrusive.

Effect of Heptylaldehyde on Spontaneous Mouse Tumours

Two years ago, L. C. Strong, working at Yale University, showed (*Amer. J. Cancer*, 28, 550; 1936) that the addition of a few drops of oil of wintergreen to the diet of mice with spontaneous mammary carcinomata produced a striking change in the tumours. They became dark owing to hæmorrhage, and this was followed by a connective tissue reaction throughout the tumour which led to a slowing of growth and a partial regression. Some of the regressing tumours, when examined on autopsy, were nothing but cystic masses containing fluid. Oil of wintergreen consists of methylsalicylate, but a repetition of these experiments with synthetic methylsalicylate failed to reproduce the results. This indicated that the effects observed with oil of wintergreen were due to an impurity. In a recent issue of *Science* (Feb. 11, 1938, p. 144), Dr. Strong records the fact that he has been able to identify this impurity as heptylaldehyde. The addition of a small amount of this substance to the diet of mice bearing spontaneous mammary tumours produced results even more striking than those observed after giving oil of wintergreen, namely, liquefaction and regression of the tumour. Out of 25 mice with spontaneous mammary tumours, complete regression occurred in five mice. Dr. Strong concludes his brief communication by stating that "his investigation opens up the question that spontaneous tumours, in mice at least, may eventually be controlled by chemotherapy". The comment may be permitted that mammary carcinomata in mice are particularly liable to spontaneous hæmorrhages and that the effect of heptylaldehyde may be to intensify this tendency. Further experiments on other types of animal tumours will therefore be awaited with great interest.

Noses and Genes

THE human nose shows variety of form in the individuals of the same family as well as stabilized differences in various races of mankind. C. B. Davenport tested the hypothesis that this variation was due to the development of noses along different lines, by measuring the growth-rates of various parts of the noses of babies and older children over a period of five to twelve years (*Proc. Amer. Phil. Soc.*, 78, 61; 1937). The results show that in the case of children with unlike noses the course of development is different, but even where no indication is given at birth the nasal proportions may be quite altered by excessive growth of a particular dimension. The author interprets his findings in terms of genes: "the development of the nose is under the influence of genes, but the active genes differ at different stages in ontogeny quantitatively (in functional output) or qualitatively due to the activity of new genes like those that determine the activity of endocrine glands. Where the total gene complex is the same, as in identical twins, the result is practical identity of nose form". It is not easy to see just what addition to the facts of the analysis of form is made by this hypothetical linking of noses with genes.

Habits of Migrant Birds in Winter Quarters

IN a detailed account of migrant birds in Tanganyika Territory, R. E. Moreau discusses briefly the ecology of some British summer immigrants during their absence from Great Britain (*Tanganyika Notes and Records*, Dar es Salaam, Oct. 1937). In general, the type of territory selected for winter quarters bears a similarity to the summer habitat; swamp-dwelling birds in swamp vegetation, grey wagtails on mountain torrents, blackcaps and garden-warblers in the edges of evergreen forest, nightingales in closed bush, wheat-ears on bare soil or eroded land. Practically all the others, from willow-warblers to kestrels, favour savannah or thorn-bush. It seems likely also that certain of the birds made definite climatic preferences; the author thinks that blackcaps, garden-warblers, and swallows winter only in highland country, usually above 4,000 feet, with maximum temperatures not exceeding 86° F. (30° C.). All the immigrants to Tanganyika encounter the hot season, but, according to district, they may live in the long rains or in a period which includes a dry spell in January and February. With these climatic differences are associated differences in the abundance of the insect food upon which the vast majority of the immigrants subsist; and the fluctuations of food supply make the wintering birds less a stationary population than a collection of wandering individuals. It is interesting that the garden-warbler, which in Great Britain feeds mainly upon insects, although it occasionally takes soft fruits and berries, in Tanganyika depends largely upon small berries and, apart from the birds of prey, is the only migrant to live upon a non-insectivorous diet.

Feeding Mechanism of Lepidoptera

THE actual mode of functioning of the proboscis of butterflies and moths has long needed proper study, and various suggestions have been offered as to how the organ is manipulated. Mr. J. B. Schmitt, of the New Jersey Agricultural Experiment Station, contributes a paper on this subject which forms No. 4 of vol. 97 (1938) of the Smithsonian Miscellaneous Collections. According to this observer, the coiled proboscis of Lepidoptera is extended by means of blood pressure exerted in the stipites of the maxillæ. The pressure is brought about by the action of three pairs of muscles which, by their contraction, compress the stipites against the cranial wall. Two pairs of these muscles have their origins on the anterior arms of the tentorium while the third pair arises from the gena. By the action of these muscles, the blood becomes forced from the stipites into the cavity of each component of the proboscis, which thus becomes extended in front of the head. The coiling up of the proboscis in its characteristic manner is brought about by the relaxation of the pressure alluded to and by the contraction of diagonal muscles which cross the cavity of each component half of the proboscis. That blood pressure might be the agency for extending the proboscis has been suggested by Snodgrass who, in his "Principles of Insect Morphology", points out the mechanical analogy of the organ with the toy paper snake which a child uncoils by blowing into it. The food liquids are imbibed through the channel of the proboscis by means of a kind of sucking pump derived from the pharynx, buccal cavity and cibarium—a conclusion which is evidenced by the relationships of the muscles concerned. The details and variations in different families of the musculature of the proboscis and sucking pump are described for a number of different familes. The paper concludes with a short account of the labium and its muscles.

Studies of Brackish-water Fishes from Madras

MR. S. JONES in his paper "Observations on the Breeding Habits and Development of certain Brackish Water Fishes of Adyar, Madras" (*Proc. Indian Acad. Sci.*, 5, No. 6; 1937) gives very interesting notes on several fishes, the investigations being part of a scheme proposed for the study of the brackish water fauna of the Adyar River. Parental care has been noticed in *Etroplus suratensis*, *E. maculatus*, *Acentrogobius neilli*, *A. viridipunctatus* and *Petroscirtes bhattacharyæ*. The eggs of the two species of *Etroplus maculatus* are laid on stones or shells, the young emerging from them having cement glands on the head by means of which they fix themselves head downwards into small pits dug by the parents, which place them there after hatching. The feeding habits of the 'mud-skipper' *Boleophthalmus boddoerti* (Pallas) are described. This fish, contrary to the usual idea that it is predaceous, eats only micro-organisms, chiefly diatoms, but occasionally copepods. *Aplocheilus melanostigma* and *Panchax parvus*, on the other hand, are well known as insect larvicides. These two exercise no parental care, although the eggs in *Panchax* adhere by mucus to the ventral side of the mother.

Timber of *Eucalyptus astringens*

A FURTHER paper has now been published on the properties of Australian timbers (Pt. 2. Brown Mallet (*Eucalyptus astringens*) by I. Langlands. Div. For. Prod. Tech. Paper No. 23, Melbourne, 1937). It is stated that brown mallet has in the past been solely exploited for its bark, which is one of the richest in tan among the raw materials used in the tanning industry. It has suffered from reckless exploitation, to replace which the Western Australian Forestry Department commenced extensive plantations in 1929. The timber had not been used to any extent. The tests dealt with in this pamphlet appear to indicate that the species has outstanding mechanical and physical properties. It has comparatively small shrinkage, is almost the equal of American hickory in toughness, and is said to excel that species in static strength, though less resilient. It is considered, therefore, that it should prove a good substitute for the American timber save for the most exacting purposes.

Solanums immune to Potato Blight

POTATO growers in the plains of India are dependent upon supplies of 'seed' from Assam and the foothills of the Himalayas, in the same way that English growers rely upon Scotland, Ireland, and parts of Wales for the provision of vigorous stocks. The lowlands of India are not usually visited by the late-blight fungus *Phytophthora infestans*, but the crops upon the higher ground are often prone to its depredations. Such infestations curtail production, but have the even more serious effect of diminishing the seed potato supply to the plains. Messrs. B. B. Mundkur, B. T. Pal and Pushkar Nath have investigated the disease (*Ind. J. Agr. Sci.*, 7 (4), 627–637, Aug. 1937) with the view of controlling it by the propagation of resistant or immune host plants. Useful degrees of resistance have been found in several Indian, European and South American varieties of *Solanum tuberosum*, whilst the species *S. demissum*, *S. neoantipoviczii*, with its variety *Reddickii*, and *S. antipoviczii* were immune from the disease. They should therefore provide a promising parentage for the introduction of immunity into stocks of the potato by crossing.

Bibliography of Seismology

WITH the simultaneous issue of the last two quarterly numbers, Dr. E. A. Hodgson completes his valuable list of more than five hundred memoirs on earthquakes and allied subjects during the year 1937 (Pub. Dominion Observatory, Ottawa). As might be expected in a work so extensive, the titles as a rule are alone given, but occasionally, as in the case of Miss E. F. Bellamy's "Index Catalogue of Epicentres for 1913–1930", a useful, if brief, account is added. Lists of notes appearing in various journals, such as NATURE, *Science*, the *Engineering News-Record*, etc., are given. A welcome addition to last year's list is Mr. D. C. Bradford's bibliography of microseisms, containing the titles of 120 memoirs, the forerunner, it is to be hoped, of many similar lists. The volume ends with a subject-index, under more than fifty headings, of the year's memoirs.

Synthetic Motor Spirit Production

Political reasons continue to foster interest in methods of synthetic motor spirit production, particularly in those countries where underground petroleum resources are lacking. Low-temperature carbonization and destructive hydrogenation processes have been brought into considerable prominence during the past few years, and a great deal of time and money have been expended on their improvement. Recently a third process, known as the Fischer-Tropsch process, has begun to attract the attention of technologists, financiers and politicians alike. H. G. Shatwell, in a paper presented to the Institute of Fuel on December 7, laid particular emphasis on this somewhat revolutionary method. The origin of this process was a discovery by Fischer and Tropsch some fifteen years ago that if water gas, freed from sulphur, is passed over an alkali-iron catalyst at 450° C. and a pressure of 150 atmospheres, an oily product is formed which is known as 'Synthol'. By cracking, this can be converted into hydrocarbons known as 'Synthene'. Later, it was discovered that the oxygen content of the product could be eliminated by operating in the presence of hydrogenating catalysts at low temperatures and pressures. Improvements in technique followed as a result of detailed laboratory and large-scale research, with the result that several plants are now in process of erection on the Continent. It remains to be seen how it will compare with other processes of synthetic motor-spirit production from a financial point of view.

Reactions in Gaseous and Solid Mixtures

In accordance with the arrangements made between the Anglo-Batavian Society and the University of London, a lecture entitled "Reactions in Gaseous and Solid Mixtures" was delivered by Prof. W. P. Jorissen of the University of Leyden at the Imperial College of Science and Technology on February 21. Prof. Jorissen dealt with the limiting mixtures capable of propagating reaction in gaseous mixtures of two, three or more components and also in solid mixtures of several components. He illustrated how the behaviour of such systems could be exhibited by triangular diagrams; the different types of diagrams for the limit mixtures obtained in gaseous systems are also representative of many of the systems of solid reacting substances investigated. Similarity, for example, was shown by the diagrams illustrating the behaviour of hydrogen, chlorine, and nitric oxide mixtures with those of the systems ammonium dichromate, sulphur and iron, and the effect of nitrogen and of silica respectively on such systems. Similar relationships hold for the velocity of propagation of reaction in gaseous and in solid mixtures. In some cases, an enclosed elliptical region of reaction is obtained, in others hyperbolic curves bound the regions. Prof. Jorissen deduced from le Chatelier's equation relating to the combustion of limit mixtures that such behaviour would be expected. Among the many observations which form the experimental basis for the formulation of the behaviour of the systems investigated, may be mentioned the influence of small quantities of isoamyl bromide, 1·5 per cent of which is sufficient to prevent the combustion of methane-air mixtures under the conditions of these experiments; on the other hand, at certain concentrations, propyl bromide tended to induce oxidation of such mixtures.

Diffraction Effects due to Axial Obstructions in Telescopes

Mr. H. E. Dall has published an important paper with the above title (*J. Brit. Astro. Assoc.*, 48, 4, February 1938), in which he gives the results of his investigations on the obstruction of central rays by the prism or small mirror in the case of reflecting telescopes. He constructed artificial stars and artificial planets, making use of a low-voltage lamp for this purpose, and experimented with four types of diffracting apertures. These were as follows: that with no central obstruction, and three with central obstructions one fifth, one third, and one half the diameter of the reflector, respectively. The second and third are commonly employed for reflecting telescopes, half-diameter obstructions being rather rare. Mr. Dall supplies a considerable number of photographs for various cases, and these bring out very clearly the changes in diffraction rings, spurious disks, etc. When the central obstruction does not exceed one fifth the diameter of the aperture, there is no serious loss of detail contrasts; but in the case of close unequal double stars there is some loss of visibility. When the obstruction exceeds the above amount there is a noticeable falling off in crispness of detail, and in addition, there is an increase in spurious detail and diffraction haloes.

The Masses in Single-Spectrum Binary Systems

Prof. H. C. Plummer has recently published a paper with the above title (*Mon. Not. Roy. Astro. Soc.*, 98, 2; December 1937), in which he objects to the view expressed by Dr. R. G. Aitken in "The Binary Stars". Dr. Aitken states that the function $m_1^3\sin^3 i/(m+m_1)^2$ is frequently omitted by the computors of orbits because it gives very little definite information. Prof. Plummer is convinced that valuable information bearing on the masses of the systems can be derived in the work of obtaining orbits from single-spectrum stars, and carries out a very full investigation of the problem in his paper. The mass function determined from a single spectrum binary can be regarded as a function of $m\sin^3 i$ and the mass ratio $f = m_1/m$. It is assumed in the investigation that, within a limited range of spectral type, the mass of a star tends closely to a typical value, and no distinction is drawn between giants and dwarfs. While the adopted values of $m\sin^3 i$ are rough estimates and are systematically too large in so far as they are based on double-spectrum binaries, this is not a serious objection for the limited object in view, unless they are excessive. This latter contingency has not arisen because it would be shown in the discontinuity between the double- and single-spectrum system, and continuity in this respect is clearly brought out in the investigation. It seems a rash step to assume standard values of $m\sin^3 i$ and to apply them to individual systems, but, as Prof. Plummer points out, the results speak for themselves, and though in the lengthy Table iv they may be faulty in detail, nevertheless in broad outline they appear fairly correct.

'Spawning Urge', 'Homing Instinct', and 'Waiting' in Salmon Return

By Dr. A. G. Huntsman, Biological Board of Canada

NOT infrequently we misinterpret the mental processes of our closest friends—why they do certain things—and have to be corrected by them. If we misinterpret the mental processes of salmon, we can have no hope that they will correct us. From certain facts we may infer that salmon under the impelling force of a 'spawning urge' travel to their natal rivers by virtue of a 'homing instinct', and 'wait' at the mouths of the rivers until the conditions are right for their ascent, but we can have no hope of knowing these things, which are unverifiable assumptions. It is true that these conceptions are of very distinct value in presenting a readily appreciated picture of salmon behaviour, but are they the best for the scientific investigator? There can be no objection to them if, known for what they are, they are in quite full agreement with the facts. I do not wish to be an iconoclast, since 'images' have value, but, if they make us blind to realities, it seems desirable that we should see them as they are, even if we do not get rid of them. What are the realities?

Some years ago 'sea trout' (*Salvelinus fontinalis*) were trapped for hatchery purposes when ascending the Margaree River in Cape Breton Island during mid-summer. At spawning time, about forty per cent of these fish failed to yield spawn. We have examined this summer run and have seen that it consists in part of fish well along toward sexual maturity and in part of fish that are quite immature. To save the theory of a spawning urge, it is customary in such cases to make another unverifiable assumption—that the immature fish are carried along by the example of the others. In the Atlantic salmon (*Salmo salar*), very occasionally an immature fish is taken in summer with those that are maturing, but in the Saint John River of southern New Brunswick there is a condition in which the runs of maturing and immature fish are distinctly separated in time, so that no influence of example can be given as the explanation of the entrance of the immature into the river. There are three principal lots of fish entering the Saint John: (1) the grilse (1 + years in the sea, about 6 lb. in weight), practically all males and maturing, which enter in summer; (2) the fall or winter fish (1 + years in the sea, about 9 lb. in weight), practically all females and immature, which enter from November to January; and (3) the ordinary salmon (2–2 + years in the sea, averaging 10–15 lb. in weight, and increasing as the season advances), mostly females and maturing, which enter from May to July or August. However these facts may be viewed, there is no agreement between sexual maturity and entering the river. The gaspereau (*Pomolobus pseudoharengus*) spawns in the spring, and the mature fish enter the Margaree River at that season. But later, first the two-year-olds and then the yearlings also enter the river and pass through the estuary to fresh water, yearlings being taken even some distance above the head of tide. The conception of a 'spawning urge' inevitably obscures whatever may be the proper explanation of the return to, and ascent of, rivers by anadromous fishes.

There is a fascination in the wonderful. On the basis of certain facts and absence of facts, there has developed the view that the salmon migrates with almost unerring instinct from some distant feeding place in the sea, where salmon have never or rarely been taken, to its natal river. It is now clear that there is no known instance of a salmon making such a journey, whatever might be its mental process in doing so. It has been observed that the Atlantic salmon of the two Apple Rivers at the head of the Bay of Fundy, with a common narrow estuary, are in the outer part of the estuary, which never drains, and along the neighbouring coast, during the summer season when they are active. When sluggish in winter or when busy feeding they would not be seen. There is nothing to indicate that they have ever been in the open ocean or even out in the Bay of Fundy. They are thus more or less within the influence of the water issuing from their rivers. Under certain conditions of river discharge, usually starting in September, they go with rising tide up the estuary and into one or other of the two branches. We do not know whether each fish chooses its own branch when it reaches the fork in the estuary, but there is no necessity for its doing so, since by entering the branches at random, it has merely to remain in the right one. Certainly in the branched Miramichi estuary of northern New Brunswick, a salmon caught and 'tagged' in the Northwest Miramichi on September 24, 1930, was recaptured four days later in the Southwest Miramichi[1], having travelled nine miles down one branch of the estuary, fourteen miles up the other branch to the head of tide and twenty miles farther up above the head of tide. In any event, the salmon of Apple estuary have in an experiment shown relation to their own rivers[2]. Those of East Apple River were definitely recognizable, having been marked when descending as smolts. Traps were operated on both rivers just above the head of tide when the fish were returning. From the time when they began to ascend until close to spawning time, only marked salmon ascended East Apple River and no marked salmon ascended West Apple River. Later, however, even more marked salmon ascended the latter river than the former, so that no relation was seen near spawning time. This is the most precise experiment of the kind that has yet been reported. There is no evidence of the salmon doing anything more definite in 'homing' than to remain in the water of its own river if it happens to reach it.

Certain facts have given rise to the belief that salmon, on reaching the mouths of their rivers, 'wait' until the conditions are right, before venturing to ascend. There is no doubt that their failure to ascend is one of the great worries of the angler, and also that at times they have been seen congregated at a river mouth. While the latter observation quite fulfils the idea of 'waiting', it is only inference that they do anything more than remain there for a time, and this may be essentially the same as the behaviour of trout in a trout-pond, which congregate where the water supply rushes in. Turbulent current causes salmon to remain quiet, as a precise experiment performed this past summer clearly showed. Salmon parr in the bottom of a tank were moving about when the water was still and immediately became quiet when a current was started, resuming their to and fro movements when the current was stopped. Indeed, the usual behaviour of salmon that will ascend the river under proper conditions seems to be to go to and fro. The capture of salmon in drift nets in and near river estuaries, such as Avon River, N.S., the Petitcodiac River, N.B., and the Saint John River, is dependent upon such movements of the salmon[3]. A to-and-fro movement with a range of at least fifty miles has been demonstrated in tagging experiments[4]. The conception of 'waiting' is not in agreement with the facts.

British Industries Fair

TO anyone who has visited the British Industries Fair over a period of many years two features must have become increasingly evident. One is the extent to which scientific knowledge, methods and equipment are being used in industry, and the other the birth and growth of new industries which are the direct offspring of scientific discoveries.

At Olympia this year, the exhibits of plastics present a very good illustration of the second feature. The range and the variety of the finished plastic products available for all sorts of industrial and domestic purposes seem to increase each year. Indeed, in the prolific character of the researches into synthetic resins and kindred investigations, one is almost inevitably reminded of the fertility of the investigations into coal tar which gave birth to the vast aniline dye industry. The exhibits of plastics, indeed, now constitute one of the major features of the Fair at Olympia. Among the new products to be seen this year was a cast, phenolic resin, known as 'Catalin', which was exhibited for the first time by Catalin Ltd. The material is non-inflammable, odourless and tasteless, resistant to alcohol and oils and to most of the common acids. It is claimed, moreover, to have high di-electric and compressive strength. Catalin is not a moulded product, so that moulds, presses or dies are not required. It is supplied to the customer in cast, solid form and can be converted into the finished product by the use of standard machinery, tools and manufacturing equipment. Mouldrite Ltd. showed several samples of modern plastics, including phenol-formaldehyde, urea-formaldehyde and acrylic moulding powders and resins. The transparent synthetic product, 'Perspex', to which reference was made in the review of the Fair last year (see NATURE, 139, 380; 1937), was a prominent feature of this stand. This material is being widely adopted for use in aircraft as windscreens, cockpit coverings, cabinet windows and gun turrets. Combined Optical Industries Ltd. exhibited several examples of plastic lenses produced by special moulding processes. These included ophthalmic lenses, simple lenses, opera oculars and objectives, and camera view finders and meniscus objectives. The synthetic, plastic product used as the raw material for these optical elements is said to have optical properties that compare favourably with those of glass. In refractive index and dispersion it resembles crown glass, and it has a higher transparency than glass, especially in the ultra-violet. One most interesting feature of this new product is the number of new possibilities it creates for the use of aspherical lenses. These plastic lenses are practically unbreakable, less than half the weight of corresponding glass lenses and chemically inert.

The exhibits of chemicals were under the auspices of the Association of British Chemical Manufacturers and this section shared pride of place with the scientific instrument section. It is interesting to note that, according to the Board of Trade official statistics, home products are increasingly replacing imported chemicals. The main increases in British exports of chemicals during the past year have been in respect of bleaching powder, sodium carbonate, caustic soda, ammonium sulphate, fertilizers, dyestuffs, cresylic acid, tar, creosote oils and copper sulphate. Among a number of products, which are either new or are being offered in new form, the following may be noticed: sodium alginate—a reactive colloid used for controlling viscosity; terpeneless oils, which are invaluable in fine grade perfumery products; and a range of dyes for anodic colouring of aluminium.

The exhibit of Imperial Chemical Industries, Ltd., this year was confined to a display constituting an historical survey of the manufacture and uses of 'alkali', from the time of ancient Egypt, when it was used for glass-making and embalming, through its agricultural production in the Middle Ages, through the development of the Le Blanc process at the end of the eighteenth century, down to the introduction of the ammonia-soda process in the middle of the nineteenth century. A number of interesting historical exhibits was appropriately included in this ingenious display which, with the various notes attached to the several exhibits and with a leaflet entitled "The Story of Alkali", constituted a really fascinating and informative lesson for the visitor who had time to give careful attention to it. Attention was directed to the technical service of the alkali group of Imperial Chemical Industries, Ltd. One of the latest successes in this service has been in the refining and desulphurization of iron.

Among other exhibits in the chemicals section we may note that British Drug Houses, Ltd., showed specimens of plant hormones reproduced by synthesis in the laboratory. The Gas Light and Coke Co. showed a non-toxic tar for use on roads in the vicinity of fishing streams—an interesting example of an attempt to meet special needs.

The combined exhibit of the scientific instrument manufacturers, to which reference was made in NATURE of February 26, p. 362, was an imposing display which, as was said above, shared pride of place with the chemicals section. The layout and the arrangement of the several exhibits were dignified and effective, and those responsible for its organization are to be warmly congratulated. One general feature, which was evident at last year's Fair and still more evident this year, was the increase in the number of scientific instruments used for industrial purposes, either for routine testing, for the control of operations or in the field of scientific investigation. This tendency, it is safe to predict, will grow, and the extent to which it grows will form a fairly reliable indication of the extent to which scientific knowledge and scientific methods are permeating industry in general.

It is impossible, within the limits of an article, to do justice to all the points of interest in the combined exhibit of the scientific instrument manufacturers. Among the novel exhibits, C. Baker showed the 'Smith wear and lubricant tester'. This instrument has been designed and developed with the object of producing a reliable means of testing and investigating, by means of the same instrument, the hardness and wearing properties of various metals and also the lubricating and abrasive qualities of lubricants. Accordingly, the machine can be used to assist in the selection of the best lubricant for a given bearing or in the choice of bearing metal for a given purpose. The machine uses the principle common to certain other instruments, in which the revolving member wears a measurable impression in the flat surface of a test piece. It is, however, unique in many respects and particularly in that it employs as a wearing member a hardened steel ball of 1 cm. diameter, exactly as is used in the Brinell hardness tester. Cooke, Troughton and Simms, Ltd., exhibited several new designs of surveying instruments, in which the size and weight have been considerably reduced without loss of accuracy, and the ease of reading the circles and the general facility for handling have been increased. Among these instruments, attention may be directed to the 'geodetic Tavistock theodolite', which reads to half a second of arc. In this instrument, the mean of the readings at both ends of a circle diameter is automatically indicated. The circle graduations are permanently marked on optical glass and both circles are read from a position near the eye-end of the telescope, whichever face is being read. This firm also showed a Vickers projection microscope, for which very great stability and rigidity are claimed. It is capable of carrying specimens up to 50 lb. in weight without any risk of damage.

Adam Hilger, Ltd., showed the 'Spekker photoelectric absorptiometer'. The principal advantage of this absorptiometer over the colorimeter of the Duboscq type is that visual matching is entirely eliminated. This firm also exhibited a new large spectrograph for metallurgical spectrum analysis. It is of the Littrow type and is unique in this respect, that it is the only type of spectrograph in the world in which all the adjustments are made automatically, simultaneously and accurately. One handle only is needed to effect these adjustments. W. Watson and Sons, Ltd., showed, among other exhibits, a profile projector and the Watson-Symon 'enlarging calculator'. The latter instrument is used in the production of enlargements of the highest standard from miniature negatives. It is claimed that the instrument can be used in combination with any type of enlarger and for any size of enlargement. R. and J. Beck, Ltd., exhibited Dr. G. M. B. Dobson's 'ozone spectrometer'. It is claimed that by means of this instrument the thickness of the layer of ozone thirty miles above the earth can be measured and, from the measurement, a speedy and accurate weather forecast can be deduced. A comprehensive range of television receivers and equipment was shown on the stand of Baird Television, Ltd. The receivers incorporated a 'Cathovisor cathode ray tube', which is completely electro-magnetic in operation. A multiplier photo-electric cell was also shown and television lecture equipment for use in colleges and technical schools.

In view of the work on which the scientific instrument firms must be busily engaged in connexion with the great rearmament programme, it was no doubt difficult for many firms to exhibit at all and, for those firms who did exhibit, to give as comprehensive and detailed a picture of their industrial products as they would have liked. Nevertheless, as has been indicated, the scientific and optical instruments combined exhibit was a significant object lesson of the scope and vigour of this very vital industry.

Punjab Irrigation Research Institute[*]

The scope of the work undertaken by the Punjab Irrigation Research Institute, the director of which is Dr. E. McKenzie-Taylor, is illustrated in three publications, giving the results of different inquiries which have recently been pursued. In "The General Theory of the Gradient of Pressure under a Structure on Permeable Foundations" Mr. J. K. Malhotra and Dr. McKenzie-Taylor build up from first principles a general theory in conformity with the formulæ and values obtained by other workers for the rate of change of pressure in the direction of flow. Treating first the case of flow under a simple floor, a general expression for exit gradient is obtained, and this is extended to the case of flow under a complex structure, several specific cases being dealt with in order to show its applications.

The second of these publications takes us from the structural interests of the Institute to that of cultivation. In the Punjab, it has been the custom to regard land suitable for rice as unfit for other crops, but the improvement noted during investigations on reclaimed land tends to rebut this view. It is probable that land, which when first reclaimed is only fit for rice, can be improved to such an extent as to be capable of producing a normal rotation of crops. This is suggested in "The Soils of the Rice Areas of the Gujranwala and Sheikhupura Divisions of the Upper Chenab Canal" by Mr. M. L. Mehta.

In parts of the district referred to, the water table has risen considerably and, in consequence of the increased salt content and alkalinity, the land has gone out of cultivation. The objects of the investigation described were to determine the soil characteristics and the degree of deterioration of these lands as a first step towards their reclamation.

---

[*] Punjab Irrigation Research Institute Research Publications. Vol. 2, No. 16. Pp. 10 3 annas, 4*d.* Vol. 3, No 2. Pp. 25+iii+4 plates. 10 annas, 1*s* Vol. 3, No. 3. Pp 47+10 plates. 1·3 rupees, 1*s.* 10*d.* (Lahore, 1937)

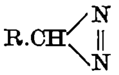
From the numerous examinations of soil samples taken, certain areas where salt and alkalinity are high were indicated as being fit, as yet, only for rice crops. Others proved to be of better quality, and it is held that the failure to appreciate this is due to lack of knowledge of the proper method of rotation, the essential feature of which is to introduce a leguminous crop immediately after the rice in order to restore the nitrogen balance. The anærobic soil conditions under which rice is grown have the result of reducing the nitrogen available for the succeeding crop. A study of the natural flora of the area showed that these gave reliable indications as to the state of the land.

This forms an interesting commentary on the third of these researches, which was suggested by the dominance of particular types of natural flora noticed in certain localities surveyed in 1931–32. The purpose of this investigation was to determine the class of soil favoured by each of the five types of vegetation selected, as a guide in future soil surveys. In "A Study of the Soil Profiles of the Punjab Plains with Reference to their Natural Flora" R. C. Hoon and M. L. Mehta deal fully with each case, and, in the result, show that four of the botanical types referred to—*Prosopis spicigera*, *Salvadora oleoides*, *Tamarix articulata* and *Capparis aphylla*—are reliable indicators of the soils they favour, and deductions may be drawn as to the crops for which they are suitable and the precautions necessary when under irrigation and treatment. In conjunction with grass (*Eleusine ægyptica*), however, a wide range of soils was found and from this type of vegetation, therefore, no index value was obtainable.

The Aliphatic Diazo Compounds

IN the forty-second Bedson Club Lecture delivered in King's College, Newcastle-upon-Tyne, Prof. J. Kenner discussed the aliphatic diazo compounds. The observation that the naturally occurring amide asparagine lost nitrogen when nitrous acid was present in nitric acid used for its hydrolysis led to the discovery of the general effect of this substance upon aliphatic amines. The work of Griess on aromatic diazo compounds was followed by the discovery of diazo acetic ester by Curtius, who turned to good account the suggestion of Baeyer that the acid part of glycine should be esterified whilst investigation of the amino group was proceeding. Together with Buchner, Curtius described the properties of the new substance which are responsible for the importance of its congeners to-day.

With regard to the formula of the aliphatic diazo compounds Curtius favoured the cyclic structure,



$$\mathrm{R.CH}\!\left\langle\begin{array}{c}\mathrm{N}\\ \|\\ \mathrm{N}\end{array}\right.$$

but Thiele was led by observations of Staudinger and himself to propose $\mathrm{R.CH} = \mathrm{N} \equiv \mathrm{N}$. Modern theory regards these compounds as examples of mesomerism, and the suggestion was now put forward that their formation from the diazo-hydroxides first produced, for example, in the preparation of diazomethane from nitrosomethylurethane, is due to the peculiar stability of the mesomeric state.

Prof. Kenner's active interest in the subject arose from his investigations of the tendency of the nitroso-group to pass whenever possible into the oximino-group. This led to an improvement of the early von Pechmann preparation of diazo paraffins, consisting in brief in the alkaline decomposition of the N-nitroso derivative of the addition product of mesityl oxide and a primary aliphatic amine.

On the larger scale, certain difficulties were encountered. Loss was occasioned by the liberated diazoparaffin combining with the mesityl oxide simultaneously formed, but was reduced by working at lower temperatures and by separating mesityl oxide from the distillate by a fractionating column. In the case of higher homologues the boiling points of which approximate to that of mesityl oxide, pulegone can with advantage be substituted for the latter, in the preparation of the nitroso compound. Ether, first used to carry away the diazo compounds, was recognized by Meerwein to inhibit their reactivity, but a very satisfactory technique was developed in which anisole is used as solvent and nitrogen as a carrier gas under reduced pressure.

Vinyldiazomethane and its methyl derivative exhibit a comparatively feeble reactivity towards acids; this was attributed to internal saturation, and in agreement with this the vinyl compound readily passes by monomolecular reaction into pyrazole.

After a discussion of some of the properties of the aliphatic diazo compounds, their chemical behaviour was discussed and more particularly towards ketones. The inertia of these towards diazomethane was first overcome when Meerwein activated acetone by means of methyl alcohol. The initial attack of the diazo compound at the carbon atom of the carbonyl group is followed by loss of nitrogen and stabilization, either by formation of an ethylene oxide ring or by a Wagner-Meerwein type of rearrangement. This latter, in the particular case of cyclic ketones, results in ring enlargement; cyclo-hexanone, for example, gives on treatment with diazomethane, 46 per cent cyclo-heptanone. Similar reactions have been carried out with the homologues of diazomethane (which are more reactive than the parent substance), and numerous 6-, 7- and 8-membered 2-alkyl cycloketones have thus been prepared. The same products were prepared directly from the corresponding nitrosourethanes by a procedure applied by Meerwein to nitrosomethylurethane, and this has the advantage of applicability in cases in which it may not be possible to prepare the diazo compound itself. By this device also it is possible to introduce groups into a ketone which may be of use in further synthetic operations.

Science News a Century Ago

Colonel John Stevens (1749-1838)

COLONEL JOHN STEVENS, of Hoboken, New Jersey, who died on March 6, 1838, although not trained as an engineer was for fifty years one of the chief pioneers of the use of steam for transport on land and sea. The grandson of John Stevens, who as a youth of seventeen went from London to New York to serve in a lawyer's office, and the son of "the Honorable John Stevens, Gentleman", a successful business man and a figure in the American political world, Stevens graduated from King's College—now Columbia University—in 1768 and for a time studied law. He was always possessed of ample means, and during the Revolution he acted as treasurer of New Jersey, attaining the rank of colonel. In 1784 he purchased large tracts of land in New Jersey, including Hoboken on the west bank of the Hudson. His interest in steam boats was stimulated by the work of Rumsey and Fitch and in co-operation with Nicolas Roosevelt and Chancellor Robert Livingston he constructed steam boats himself. Of these, the most notable was the *Little Juliana*, 1804, which he fitted with a multitubular boiler and a high-pressure engine driving twin screws. This was the first practical screw-driven steam boat. The machinery of the boat is preserved in the United States National Museum.

In 1807, Stevens constructed a paddle wheel vessel the *Phœnix*, which made a trip from New York to Philadelphia, this being the first voyage by a steam boat in the open sea. Later on he started a steam ferry-boat across the Hudson. He wrote much on the improvements of roads and was a prominent advocate of steam railways. In 1815, he applied for and received from the State of New Jersey the first American railway charter, and when seventy-six years of age constructed the first locomotive in America and ran it round a circular track on his estate. He retained his mental vigour to the last. Of his family, John Cox Stevens, Robert Livingston Stevens and Edwin Augustus Stevens also did much for furthering transport in the United States, and the last, by his will dated 1867, provided for the erection and endowment of the well-known Stevens Institute of Technology, Hoboken, N.J.

Structure of Vegetable Tissue

ON March 8, 1838, the Rev. Joseph Bancroft Reade (1801–70), the chemist and microscopist, read a paper to the Royal Society entitled "An Inquiry into a new Theory of Earthy Bases of Vegetable Tissues". After briefly noticing his experiments described in two papers in the *Philosophical Magazine* of July and November 1837, he adverted to the theory of M. Raspail detailed in his "Tableau Synoptique" and "Noveau Système de Chimie". In opposition to some of the views entertained by Raspail, Reade found that in the bark of the bamboo and the epidermis of straw the silica incrusting these tissues is not crystallized, but on the contrary exhibits, both before and after incineration, the most beautiful and elaborate organization, consisting of an arranged series of cells and tubes, and differing in its character in different species of the same tribe and in different parts of the same plant. The observations of Mr. Golding Bird were referred to, and Reade stated in confirmation that, by employing caustic potash, the siliceous columns may be removed from the leaf of a stalk of wheat, while the spiral vessels and ducts which form the principal ribs of the leaf, as well as the apparently metallic cups, which are arranged on its surface, remain undisturbed. He proposed, therefore, to substitute, in the description of vegetable tissues, the term skeleton, instead of that of bases, whether saline or siliceous, of those tissues.

The Mass of Uranus

AT a meeting of the Royal Astronomical Society on March 9, 1838, a paper by Dr. J. Lamont was read on the "Value of the Mass of Uranus deduced from Observations of its Satellites made at the Royal Observatory of Munich during the year 1837". In the course of the year, opportunity of a few favourable nights was taken to observe the satellites with the view of calculating the mass of the planet. Though the object was not satisfactorily attained, the results were not without interest as it led to the conclusion that the true mass of the planet was considerably smaller than that generally adopted. The value he found was 1/24605, being less by one fourth part than that obtained by Bouvard, from the perturbations produced by the planet. Lamont remarked that in giving this value he was aware of the uncertainty of the data on which it rested. He was confident that the value of the mass of Uranus, then used in the theory of the planetary perturbations, ought to be greatly diminished, though the precise proportion in which this should be done could not then be assigned.

Lamont was born on December 13, 1805 at Muckle Inverey, near Braemar, Aberdeen, but at the age of twelve years was sent to the Scottish Benedictine Monastery at Ratisbon, Bavaria. He was made director of the Munich Observatory in 1835, devoting much of his time to terrestrial magnetism. He died at Bogenhausen, Munich, in August 1879. In September 1934, Princess Arthur of Connaught unveiled a memorial to him at his birthplace.

Whewell's "History of the Inductive Sciences"

IN a long review, in the *Athenæum* of March 10, 1838, of Whewell's three-volume work "History of the Inductive Sciences from the Earliest to the Present Times", the reviewer towards the end of his article proceeded "to endeavour to pronounce at once a distinct opinion on the merits of the work before us. We find," he wrote, "in that work abundant proofs of profound and varied knowledge, great power of language, impartiality of judgment, and even boldness of thought; but unfortunately the ambition of eloquence seems to have enticed the author into a style not always the most appropriate to his subject. His style is that of one whose mind is used not to originate, but to receive ideas—not to unfold, but to grasp them: in his efforts to express himself clearly he usually becomes sententious. He leans towards transcendental truths and expressions; and while from its want of elemental ideas and simple language, his work will be always unintelligible to the bulk of people, we fear that those who by their knowledge of physical science are capable of understanding it, may have reason to complain of its want of originality and acuteness, of breadth of view and insight into the reciprocal action of the various branches of human knowledge; or to lament that it chronicles the increase of science, without throwing much light on the history of the human mind."

University Events

Birmingham.—The Poynting Memorial Lecture will be given on March 11th at 5.30 p.m., at the University, Edmund Street, by Dr. E. C. Bullard, who has chosen as his subject "Geophysical Measurements at Sea". The lecture will be open to the public.

London.—Prof. G. M. Bennett has been appointed professor of chemistry tenable at King's College. Since 1931 he has been Firth professor of chemistry in the University of Sheffield (see also p. 403).

Mr. R. S. Pilcher has been appointed professor of surgery at University College Hospital Medical School. Since 1934, he has been first assistant in the Surgical Unit and, since 1936, assistant surgeon at University College Hospital.

The title of professor emeritus of pathology in the University has been conferred on Prof. A. E. Boycott, formerly Graham professor of pathology in University College Hospital Medical School.

The following doctorates have been recently conferred: D.Sc. in chemistry on E. D. Hughes, of University College, and W. Taylor, of the Sir John Cass Technical Institute; D.Sc. in physics (spectroscopy) on W. H. J. Childs, of King's College.

The following, among others, have been appointed fellows of King's College: Mr. E. R. Bolton, a member of the Chemical Engineering Committee; Lieut.-Colonel R. D. T. Alexander, president of the Institution of Engineers (India) in 1928.

Among those recently elected to the fellowship of University College, London, are: Dr. E. J. Allen, formerly secretary of the Marine Biological Association of the United Kingdom, and director of the Association's laboratory at Plymouth; Dr. H. L. Eason, principal (formerly vice-chancellor) of the University of London; Prof. E. Mapother, medical superintendent and professor of psychiatry at Maudsley Hospital; Mr. A. S. Quartermaine, assistant chief engineer of the Great Western Railway; Mr. C. C. Walker, chief engineer of the De Havilland Aircraft Company; Mr. C. S. White, senior obstetric surgeon in University College Hospital; Mr. J. A. Wilks, librarian of University College.

St. Andrews.—The following appointments have recently been made: H. G. Campbell to be the first professor of dental surgery; G. A. Cumming to be lecturer in geology and geography; J. Dewar to be lecturer in chemistry in the United College; Dr. D. Stiven to be lecturer in bacteriology and assistant director of the Bacteriology Laboratory.

Societies and Academies

Paris

Academy of Sciences, January 10 (*C.R.*, 206, 81–136).

Lucien Cayeux: The role of the Foraminifera and of calcium carbonate in the fixation of certain mineral substances.

Jean Cabannes and Auguste Rousset: The Raman effect in gases under pressure.

Marcel Godchot and Mlle. Germaine Cauquil: The menthadienic hydrocarbons obtained in the dehydration of the active and inactive 1-methyl-3-cyclohexylisopropyl pinacones.

Ernest Vessiot: The equations $F(x,y,z,p,q,r,s,t)=0$ to which the method of Darboux is applicable.

Henri Poncin: The commencement of flow of a viscous fluid.

Léopold Escande: Flow through a gate valve.

Pierre Dive: The impossibility of permanent barotrope rotations in a fluid star with ellipsoidal stratification.

Raoul Goudey: Measurements of the acceleration of gravity made in France during the year 1934. Values of g for 58 places in France are tabulated.

Henri Lacoste-Tayan: The aerial *permeance* of permanent magnets.

Mlle. Sylvanie Guinand and Jacques Nicolle: The rotatory power of mixtures of ascorbic acid and soda.

Frantz Perrier: The radiation emitted by solid dielectrics electrified by friction. The existence of this radiation having been doubted by Eichenberger, additional experiments made with further precautions as regards screens are described. The author still upholds the reality of the radiation.

Mlle. Yvette Wormser: The action of oxalic acid on a cobaltichloropentammine.

Marcel Frèrejacque: The identification of glucose. The acetolysis of the glucosides. The method is based on the production of β-tetracetylglucosylparatoluidine. This has definite and easily recognizable properties, and can be made from the products of hydrolysis of a glucoside without difficulty.

V. Dolejšek and M. Jahoda: The variations of the network of piezo-electric crystals produced by a static electric pressure.

Marius Dalloni: The Permian deposits of the Pyrenees with Angaride flora.

André Lenoble: The age and chronological order of the eruptive outbreaks between Mahanoro and Nosy-Varika (eastern coast of Madagascar.

Gaston Delépine and Branko Yovanovitch: The presence of Famennian grit and coralligenous limestones of the middle Devonian at Mechra ben Abbou (western Morocco).

Paul Deleau: Sudden variations of facies of the lower Cretaceous at Djebel Djaffa (Constantine).

Ottavio Munerati: The culture of the beetroot from seed to seed in a simple liquid medium.

Roger Gautheret: Transplanting cambium tissue cultures of *Salix caprea*.

Constantin Dawydoff: Asexual multiplication by laceration in *Ctenoplana*.

Marius Piéry, Jean Enselme and Mlle. Simone Petel: Researches concerning the influence of mineral waters on tissue respiration. Role of the ions Ca^{++}, Mg^{++} and Na^{+}.

Mme. Andrée Roche, Jean Roche, Mme. Simone Drouineau and Paul Passelaigue: Capability of a protein food to meet the nitrogenous needs of maintenance or of growth and regeneration of tissue proteins.

Serge Tchakhotine: Ultra-violet ultra-micropuncture: a new means of studying colloidal phenomena in the living cell.

Geneva

Society of Physics and Natural History, October 21.

Paul Rossier: (1) The apparent diameter of the star α-Leonis. The author shows that the various formulæ proposed for calculating the apparent diameter of a star agree with the results of observations made by Arnulf and based on the method of occultations. This result is the more remarkable since it has been obtained by examining a hot star. (2) The separating power of the prism objective. It is easy to prove that the separating power of the prism is slightly below that of the objective and that these two objects agree with each other if their diameters are equal. As the dispersion increases with the angle of the prism, it would appear to be advantageous to increase this angle as much as possible. In reality, for photometric reasons, this is made relatively small.

November 18.

Jean Louis Perrot : The descent of the ovocytes in *Helix Pomatia*. The receptivity of the ovocyte does not appear to be connected with a determined stage of maturation, but rather on its position in the genital tract. Whatever may be the state of nuclear division of the ovocyte, it is fertilized only when it has penetrated into the fertilizing chamber.

Max Perrot : Researches on the chromosomes of the *pulmonés stylommatophores*. The results of numerous counts of chromosomes carried out especially in the Helicidæ family leads the author to attribute to the sub-family of the Helicinæ the characteristic chromosome numbers 22, 25, 26 and 27.

Emile Cherbuliez, Jean Jeanneret and Kurt H. Meyer : Collagen A, collagen B and gelatin. A study of the fibres of calf's foot tendon has shown that in the passage from the original collagen to gelatin two sorts of transformations must be distinguished. First, a physical transformation consisting of a loss of the crystalline structure of the primitive fibres, and secondly, a chemical transformation characterized by a commencement of hydrolysis which splits up the long polypeptic chains. The usual collagen B is a product arising from collagen A by an intra-micellular fusion (transformation 1) accompanied by a beginning of hydrolysis of variable intensity depending on the treatment adopted. Hence collagen B is not a product showing constant properties.

December 2.

Arnold Lillie and Willy J. Schroeder : The Nummulitic of the valley of Chambres (Nappe de Morcles, Samoéns Alps, Haute-Savoie). The detailed study of a Nummulitic series shows (1) the presence of a fauna of foraminifera altered from the Upper Cretaceous ; (2) a Lutetian marine intrusion ; (3) a series of red intermediate layers between the marine Lutetian and a complex conglomerate series ; and (4) a complex conglomerate series intermediate between the Lutetian layers containing Lutetian nummulites and those containing Priabonian nummulites.

Augustin Lombard : Polygenic conglomerates of the base of the external Pre-Alps (Voirons, Pléiades, Collines du Faucigny). (1) Distribution, lithology. Conglomerates are found at Voirons analogous with those discovered in the external Pre-Alps. They are arranged in a series of lenses in contact with the molasse and the ultra-Helvetic flysch. (2) Problem of their origin. The polygenic conglomerates of Voirons are detritic Taveyannaz grits of Priabonian age transported over a distance of about 30 kilometres, and autochthonous formations identical with those of Clusaz.

Charles G. Boissonnas : The calculation, for a binary mixture, of the partial vapour pressures starting with the total pressure. The knowledge of the total pressure of the vapour in equilibrium with a binary solution, as a function of the molecular composition of the condensed phase, suffices for the calculation of the partial pressures.

A. J. A. van der Wyk : The viscosity of binary mixtures. It is impossible to describe the viscosity of a mixture without the introduction of a new magnitude called 'binary viscosity', some applications of which are indicated.

Madeleine Blanc and Jean Weigle : Simultaneous reflections and deflected action. It can be shown that the intensity of the apparent reflection of X-rays on planes with zero coefficient of reflection can be of the same order of magnitude as on planes with the coefficient not zero. The energy which flows in the originally inhibited direction cannot arise directly from the incident wave.

Jean Weigle : The double refraction of an atomically stratified medium. Waves propagated in a stratified medium give double refraction. The velocities of the resulting waves are represented by an ellipsoid and by a sphere which are the Fresnel surfaces.

Jean Patry and Jean Weigle : The conditions at the limits in problems of diffraction by periodic media. The authors have established the conditions at the limits, in a periodic medium traversed by waves, that determine those of the waves which will be excited by an external wave falling on the medium.

Rome

National Academy of the Lincei (*Atti*, 25, 679–746; 1937).

F. Severi : Systems of equivalence of any species on one algebraic variety, as rational systems (2).

G. Scorza : Algebras linked to groups of finite order.

S. Cherubino : Application of holomorphous functions of matrices to systems of linear differential equations (2).

M. Villa : Differential property of the cones of Veronese.

G. Colonnetti : Elastic equilibrium of systems in which non-elastic deformations also occur (4).

E. de Angeli : Some integrable cases of movement of a heavy asymmetric gyroscope.

F. de Franchis : Links and reactions in the most general scheme of Lagrange.

M. G. Fracastoro : Eruptive protuberance of May 29, 1937.

G. Boaga : Relationships between the deviations of the vertical and the gravimetric anomalies.

A. Baroni : Sulphur selenium protochloride. Determination of the index of refraction and of the surface tension of mixtures of sulphur in selenium protochloride Se_2Cl_2.

C. Perrier and E. Segrè : Some chemical properties of element 43.

G. Piccardi : Flame spectrum of europium and the persistence of three lines of low excitation.

P. Comucci : A singular rock from the Baltoro glacier (Karakorùm) (2).

E. Marchesini : Extension of the Oligocene in the region north-east of the Monte Judica group (Provinces of Catania and Enna).

T. Perri : Researches on the histological modifications of the thyroid in the guinea pig during the œstrus cycle.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, March 7

University of London Animal Welfare Society (at University College, Gower Street, W.C.1), at 5.15.—Dr. A. H. B. Kirkman: "The Disappearing Fauna of Africa: a Tragedy".*

University of Leeds, at 5.15.—Prof. E. K. Rideal, F.R.S.: "Some Recent Advances in Surface Action".*

Royal Geographical Society, at 8.30.—M. Hubert Carton de Wiart: "The Pan-American Highway Project".

Tuesday, March 8

King's College, London, at 5.30.—Prof. A. J. Allmand, F.R.S.: "The Drumm Storage Battery".*

University College, London, at 5.30.—Prof. P. Pruvost: "Some Problems of Sub-Surface Geology in Northern France" (succeeding lecture on March 10).*

Pharmaceutical Society, at 8.30.—F. W. Gamble: "Facing Realities" (Harrison Memorial Lecture).

Thursday, March 10

University College, London, at 5.—Prof. P. E. Verkade: "The Role of Dicarboxylic Acids in Metabolism".

Friday, March 11

Physical Society (at the Imperial College of Science and Technology), at 4.45.—Annual General Meeting.

University of Birmingham, at 5.30.—Dr. E. C. Bullard: "Geophysical Measurements at Sea".*

Institute of Metals, March 8–10.—Annual General Meeting to be held at the Institution of Mechanical Engineers.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned.

Assistant Engineer in the Roads Department of the Ministry of Transport—The Assistant Secretary, Establishment Department, Ministry of Transport, Metropole Buildings, Northumberland Avenue, W.C.2 (March 7).

Head of the Chemistry Department of the Wigan and District Mining and Technical College—The Principal (March 8).

District Agricultural Organiser for the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the Council, County Hall, Chelmsford (March 11)

Lecturer in Mechanical Engineering in the Croydon Polytechnic—The Education Officer, Education Office, Katharine Street, Croydon (March 12)

Research Officers for investigation into contagious abortion and swine fever and necrotic enteritis at the Veterinary Laboratory, New Haw, Weybridge—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (March 14).

Agricultural Instructor in Wiltshire—The Clerk of the Council, County Offices, Trowbridge (March 15).

Lecturer in Charge of the Textile Department in the Belfast College of Technology—The Director of Education, Victoria Street, Belfast (March 21).

Assistant Director of Clinical Investigations and Research (University of Manchester) in the Manchester Royal Infirmary—The Registrar, University (March 27).

Lecturer in Biochemistry in University College, Dundee—The Secretary, The University, St. Andrews (March 28).

Deputy Water-Works Engineer to the British Municipal Council, Tientsin—Messrs. J and A. Leslie and Reid, Civil Engineers, 72A George Street, Edinburgh, 2 (March 30).

Assistant Keeper in Entomology in the Manchester Museum (University of Manchester)—The Registrar (April 20).

Lecturer in Biology (woman) and part-time Lecturer in Geography (woman) in the Southland Training College, Wimbledon Park Side, S.W.19—The Principal.

Professor of Chemistry in University College, Dundee—The Secretary, The University, St. Andrews.

Interpretation and Exposition of Scientific Research

ONE of the most important tasks of the Department of Scientific and Industrial Research, in the view of the Advisory Council, as indicated in the report of the Department for 1936–37, a summary account of which appears on p. 432, is to organize the conduct of research so as to promote contact with industry. Particular attention is given to this question of contact with industry in a number of the recent reports of the Advisory Council, and one reason for attaching importance to the development of the research association movement is the opportunity it affords for the industrialist to state his problems to the man of science and to determine the order of priority, in terms of their economic importance, of the objectives of particular proposals for research.

The success of the Department in fostering co-operation with an even wider range of industries and interests than is represented by the research associations is well illustrated by the work of the Water Pollution Research Board, the first ten years' work of which is reviewed in some detail in the latest report of the Advisory Council. In spite, however, of all that the Department has done to promote the application of results by industry, British industry still appears to lag behind industry in the United States.

Special attention is directed to this point by the Advisory Council in commenting upon a visit paid last year to Great Britain by a party of some thirty American business men and bankers who came to take stock of the conditions under which research is carried out here, and of the organization adopted to promote the practical application of its results. The visit was organized by the Division of Engineering and Industrial Research of the National Research Council of America, and after spending a fortnight in England the visitors proceeded to France and then to Germany, where they made similar inquiries. In Great Britain, the arrangements for visiting laboratories were made in close co-operation with the Department of Scientific and Industrial Research. The strenuous programme included visits to the Science Museum, the National Physical Laboratory, the Fuel Research Station, the Building Research, the laboratories of four research associations and of five representative industrial corporations as well as to the Cavendish Laboratory, Cambridge.

The tour was arranged primarily for the information of business men and bankers whose chief interest in the laboratories they visited was the utilitarian requirements of commerce and finance. The tour provided a striking object lesson in the keenness of industrial management in the United States to ensure that no opportunity is lost of turning science to the advantage of its business, and in commenting on the tour the Advisory Council refers to the necessity in Great Britain of giving more attention to the presentation of the progress of industrial research to what are described in the United States as the executives of business. What is here required is the presentation, not so much of scientific data, as of their industrial and financial implications, and in reviewing the various aspects of the publication policy pursued by the Department, the Advisory Council raises again the question of the interpretation of the results of scientific research which has an ever-growing importance.

A first objective in the publication policy of the

Department is, of course, the provision of the full scientific data of the researches carried out so that the technical man can judge of their value for himself and apply them in his own industry. To a large extent, this need is already admirably served by special reports published on behalf of the Department by H.M. Stationery Office, as well as by papers read before the learned and technical societies and by special articles contributed to technical and trade journals. Indeed, many of the reports and papers emanating from the Department set an admirable example of lucidity of exposition which could be followed with advantage by other scientific workers in presenting the results of their work.

Increasing attention is being paid by the technical Press to the activities of the Department, and this not only in itself promotes the dissemination of the reports themselves but also provides one means of presenting the work to the executive leaders of industry. There can be no doubt that in the last few years the interest of the general Press in scientific news has greatly increased, and already in the United States of America Science Service has been developed to render expert assistance to the Press in this field and particularly to overcome some of the difficulties encountered in presenting scientific news in a form which can be understood by the public.

Industrial research has its own special difficulties in this matter. The germ of an industrial advance is usually found in a discovery in the laboratory, but its development and final applications to industry may take a long time. Great caution is accordingly always necessary in the presentation of the initial discoveries before their industrial applications have been explored and tested. Apart from the hampering effect of premature disclosure on technical development, which is often much less serious than is supposed, unfulfilled prophecies are themselves liable to be detrimental to the general application of research. On the other hand, when the necessary reserve and caution are used in announcing the early stages of some new work the result often makes dull reading whether to the business executive or to the man in the street.

For these reasons, the Advisory Council attaches more importance to the fact that the Press is doing its utmost to stress the value of research in national development. It should be obvious, however, that the tasks of presenting results to business executives and also to the ordinary tax-payer, who provides the major part of the Department's expenditure and has every right to be told how the results are of benefit to him and to the nation as a whole, are by no means identical. For both purposes, the results must be expressed in non-technical language, but the content and emphasis required in the exposition are very different.

We have here a problem to which scientific workers, whether in industry or not, might well give more attention. Nor is it a problem for them alone. Fundamentally, it is one of co-operation between the technical or scientific worker and the Press, only to be solved as mutual understanding and respect are established. Although the Press in Great Britain has not moved anything like so far in the utilization of scientific men for the collection and editing of news as in the United States, and generally gives less care and thought to the presentation and accuracy of scientific news than to most other specialized activities, generally speaking it is much more alive than formerly alike to the significance and importance of scientific work and to the difficulties in the way of its accurate exposition or interpretation. In fact the first need to-day is probably for a greater response and willingness to co-operate on the part of the scientific worker himself.

Much is indeed involved in such co-operation. In the first place, there is still far too much jargon and loose expression in scientific or technical papers. It is true, of course, that the scientific investigator is entitled to use the same vocabulary as other workers in the same field when addressing himself to a scientific society, but unfortunately insufficient care is often taken in regard to the introduction of new terms even here. Moreover, many scientific workers are guilty of confused thinking and want of care in arranging their ideas in logical sequence or in expressing them concisely.

Such careless writing places difficulties in the way of the appraisement or evaluation of the work of the scientific investigator by his own colleagues and still more in its interpretation to the non-technical man or general public. The scientific worker has to remember that his work has not fully achieved its purpose until it is understood and can be integrated into the general body of knowledge of the science or industry.

This in turn demands from the scientific worker not only a much greater respect for accurate and lucid writing, and more whole-hearted attempts to see that the careless use of words does not invalidate accurate and painstaking experimental work but also an appreciation of the position and work of the expositor and in particular of the work which the Press is trying to do. High ability in research and felicity of exposition are by no means always linked in the same person, and investigator and expositor have each their place to fill and merit their own reward. The lack of regard of scientific men for some of the ablest expositors in their own ranks is probably one reason why science is not so widely and well served in that respect as is desirable.

If most scientific workers have little desire or capacity to transform the special vocabularies of their subjects into the simpler and not necessarily sensational forms required by the general reader, remembering these things, they should be more grateful for the service rendered to science itself by those who are able to present a scientific subject accurately and attractively in a literary style.

Fundamentally, therefore, this question of publication turns on education, both that of the man of science in the capacity to express himself in terse and lucid English, and that of the general member of the public, whether of the Press or not, so that he has a general scientific background against which to set scientific or technical progress as it is made known. Both aspects are of importance, but it would be a mistake to imagine that the printed word is the only means by which the results of scientific work can be brought before the community.

One such method is seen in exhibitions organized by the Department of Scientific and Industrial Research to show the results of its research. Already a number of such exhibits has been arranged: at the Smoke Abatement Exhibition in the Science Museum, at the Public Health Exhibition in the Royal Agricultural Hall, at the Engineering Exhibition in Greyfriars Hall, Cardiff, at the Building Centre and at the Exhibition of Testing Plant and Apparatus at the Institution of Civil Engineers and at the Engineering and Marine Exhibition. The Advisory Council considers that this activity provides an excellent means of forming contacts between the staff of the Department and those engaged in industry, and assists in making better known the facilities available in the Department for co-operative research and for dealing with special inquiries.

The method is of course already in use by many industrial firms both in connexion with their technical service work and to make known the results and scope of their research, as in that recently organized by Imperial Chemical Industries Ltd., in connexion with the opening of the new research laboratories at Blackley, Manchester. Other examples are to be found in the special exhibits arranged at the Science Museum and elsewhere, and the success they have achieved indicates that exhibits of this type offer a very valuable means of bringing the results of scientific and industrial research before the general community.

In connexion with the preparation for exhibits, the Department of Scientific and Industrial Research has recently begun to make short films dealing with the work. These films have already proved of great value in illustrating lectures given all over the country by officers of the Department and they are in some demand by technical societies. Here again is a medium of education and exposition to which scientific workers might well give more attention, while the series of talks which from time to time have been broadcast under such titles as "What more do you want of the scientist?" or Dr. Julian Huxley's talks on scientific research and social needs indicate yet another medium which science itself has placed at their disposal.

The reference to these matters in the Advisory Council's report is the more welcome because the lack of unity in the profession of science makes it difficult to utilize the opportunities of interpretation and exposition which are in these ways offered to the world of science. The Department indeed is probably in almost a unique position in its capacity and ability to interpret to the world of industry and to the community generally the results of both pure and applied scientific research. Already its publications indicate an attention to the art of exposition and interpretation which are seldom elsewhere paralleled in the scientific world, except in the technical publications issued by the publicity departments of a number of our more progressive industrial firms—publications themselves insufficiently appreciated by scientific workers. With a little more support and co-operation from scientific workers generally it should not be impossible for the Department to explore even more widely the possibilities not only of publications but also of such other media as exhibitions, the film or the broadcast talk in interpreting to the ordinary citizen the significance and meaning of the achievements of scientific and technical research. At least it may be hoped that the latest report of the Advisory Council will again direct the attention of scientific workers to a question which has far too often been neglected or disdained.

Science in Industry

THE twenty-second report of the Department of Scientific and Industrial Research*, which covers the period October 1, 1936–September 30, 1937, includes the report of the Committee of the Privy Council signed by Lord Halifax, and the longer report of the Advisory Council signed by Lord Riverdale, together with a summary of the work of the National Physical Laboratory and other research stations and research boards and brief reports from the various research associations. Both the report of the Advisory Council and of the Committee of the Privy Council pay tribute to the work of Lord Rutherford, whose last act as chairman of the Advisory Council was to shape the report which is now submitted. The present report once more displays the impressive contribution which the work of the Department makes to every aspect of our national life.

The expenditure of the Department in 1936-37 was £830,180 gross or £583,230 net as against £571,831 net in 1935–36. The largest single item of expenditure was £105,589 on the National Physical Laboratory, compared with £109,038 in 1935–36, the gross expenditure of £244,081 covering, however, the cost of work carried out at the laboratories of the Food Investigation Board, the Radio Research Board, the Road Research Board and other research boards of the Department. Against this gross total, receipts amounted to £138,492, of which £67,863 represents fees from industry for paid work. The total receipts from industry for the work of the Department, including contributions to co-operative research, amounted to £106,250, while a further £77,101 was received from other Government Departments for services rendered, £35,035 from the Road Fund and £9,543 from the Empire overseas for food investigation. Expenditure on fuel research was £105,660 gross or £92,809 net, on building and road research £87,957 gross or £32,264 net, on the Chemical Research Laboratory £21,146 net, on forest products research £39,382 net and on the Geological Survey and Museum £68,449. Almost the whole of the expenditure of £10,613 on water pollution research was covered by receipts amounting to £9,215, while £15,928 was received against the gross expenditure of £54,926 on food investigation. Grants to research associations, etc., amounted to £126,510 as against £108,951 in 1935–36 and £85,384 in 1934–35, and the report notes the formation of a new Research Association by the Pottery Manufacturers' Federation, to which the Department has made an annual grant of £5,000.

Special stress is laid in the report of the Advisory Council on the work of the Water Pollution Research Board, which has now completed ten years work and in that time has succeeded to a remarkable extent in bringing about a realization of the community of interest in all concerned and in establishing scientific research as the true servant of all parties. The intensive survey of the River Tees and of the effects of the discharge into it of large quantities of sewage and of industrial effluents has led to the discovery that the true cause of the killing of smelts in the estuary is cyanide in coke-oven effluent. Further, it has been found that this cyanide can be readily converted into the much less toxic ferrocyanide if it is treated with spent pickle liquor and lime. At the same time, the suggestion has been put forward that modified methods for cooling and washing coke-oven gas and the use of any remaining waste waters to quench coke would greatly reduce the quantity of the discharge. This suggestion has already been followed in a large installation of coke ovens recently erected at South Bank on the Tees.

This notable survey, with its demonstration of the possibility of reconciling the community's requirements in regard to pure water supply and the industrial disposal of effluent, has already led to a further investigation of the effect of crude sewage discharge on the navigability of the Mersey, which has just been completed. Successful work has also been carried out on the treatment of effluent from beet-sugar factories and from large dairies, while at the Chemical Research Laboratory the Board has sponsored studies of the softening of water, in which certain synthetic resins have given promising results.

This review of the work on water pollution well illustrates the cumulative effect of such investigations as a body of knowledge is built up which can be readily applied to the solution of allied problems as they arise, and the recent typhoid epidemics at Croydon and elsewhere emphasizes the importance of constant scientific control if a pure water supply is to be secured. So, too, in the field of atmospheric pollution the Department is steadily acquiring scientific data on the extent and distribution of pollution and is making a special survey of the city of Leicester which should ultimately provide the basis for effective action to diminish the toll at present taken of health and general welfare in industrial centres by this cause.

---

* Department of Scientific and Industrial Research. Report for the Year 1936–37. (Cmd. 5647.) Pp. iv+195. (London: H.M. Stationery Office, 1938.) 3*s.* net.

Passing from water supply and air to food supply, we find the Department making equally significant contributions. The researches of the Food Investigation Board have ranged, for example, from the study of storage problems such as the value of ultra-violet light in prolonging the storage-life of meat, the effect of the concentration of carbon dioxide in the atmosphere in which eggs are stored, the diminution of 'store-burn' in the storage of poultry, the cold storage of herrings, the gas-storage of pears, strawberries and other fruits, to the chemical composition of wood smoke used in curing fish, the effect of muscular exertion on the chemical composition of muscular tissue and the keeping quality of bacon. Further trials have confirmed that freshly caught white fish can be brine frozen, glazed and stored so that after four to six months the fish is highly palatable, suitable for smoke curing and substantially unchanged. Of special interest are the results obtained from a further scientific expedition to Australia and New Zealand to study the performance of the new 'jacket' system of refrigeration developed at the Ditton Laboratory of the Department. The full data obtained are still being examined, but the new system appears to be working satisfactorily. In the great bulk of a stack of 50,000 cases of apples the temperature was uniform within 0·5° F., and with the new system about 3,000 more cases could be carried than with normal storage.

The bearing of these results on food supply and particularly in view of the increased importance of storage questions should be obvious to all whether in relation to national defence or to the questions of quality or public health. Equally important work is, however, being carried out in this field by a number of research associations. The Research Association of British Flour Millers has succeeded in developing a machine for measuring and recording graphically the baking quality of flours and a full-scale plant has now been erected for improving the baking quality of flour and the crumb quality of the bread by treatment with hot damp air according to the process developed in 1928. Other investigations of the Association have related to the nutritive value of bread and the place of bread in the dietary. The Research Association for the Cocoa, Chocolate, Sugar Confectionery and Jam Trades has investigated the resistance of cacao butter to oxidation changes with the view of avoiding the stale flavours associated with such changes, as well as the mechanism of pectin jelly formation by fruits, and is making a special study of toffee manufacture as well as of the protection of cacao beans, nuts, dried fruits, etc., against storage pests. The Food Manufacturers Research Association has been responsible for investigations on the curing of bacon by a new method, the quality of gelatin used for meat products in glass cases, and the cause of white deposits on fish preserved raw by packing in salt.

Turning from food supply to fuel and lighting we find an equally impressive record of service rendered to daily needs. Besides the physical and chemical survey of the national coal resources and the study of the hydrogenation of coal with its bearing on the more effective utilization of coal whether primarily as fuel, as motor spirit or as lubricating oil, the work of the Fuel Research Board is making such incidental contributions as the study of possible improvements to the domestic grate, particularly from the point of view of smoke reduction and increased efficiency and the preparation of coal for the market including its 'dust-proofing' to eliminate the raising of dust when the coal is handled. In the field of lighting, the work of the Department touches the life of the ordinary citizen at many points both inside his home and out. Besides, for example, the investigations on daylight problems in clerical work and on the relative merits of light of different colours for various visual tasks, or the work of the National Physical Laboratory on the standardization of electric lamps, the work of the Department in this field has had a most important bearing on road safety. A report issued by the Department has shown that the claims made for a coloured headlight beam for motor-cars in place of a white beam cannot be substantiated, while an investigation concerned with the question of the best colour for street lighting has led to the development of a photographic means of reproducing the actual street scene in all the details affecting an observer's ability to pick out objects in the street which appear and disappear on the surface of the lighted street.

The motorist will indeed find much else that is of interest in the work of the Department, for the Road Research Board's investigations cover such problems as that of skidding, the testing of road surfacing materials, the stresses imposed by all kinds of tyres. For the study of skidding an ingenious apparatus has been developed for taking surface texture prints of a road, while another ingenious apparatus the 'wet road clock' has been developed for recording the periods during which a road was wet, in carrying out tests on the durability of a road. At the National Physical Laboratory, the Department is investigating, too, the noise of motor horns with the object of correlating offensiveness with special physical features, and important research on cylinder wear initiated by the Department in co-operation with the Institution of Automobile Engineers is nearing completion, while the Research Association of British Rubber Manufacturers has completed an investigation on the ageing of the inner tubes of motor tyres, in which the accelerated tests of ageing have been correlated with natural ageing.

The work of the Building Research Station makes many important contributions to the comfort of the home, both indirectly in its fundamental studies of the properties of building materials such as cement, asphalt, limes and plasters, bricks, roofing tiles, etc., all of which ultimately lead to the construction of more satisfactory houses and also through its studies on the efficiency of buildings from the point of view of the user. The new heating laboratory has carried out extensive tests with hot water radiators as well as on heat transmission through walls and the thermal conductance of windows and a definite programme of work on ventilation has also been undertaken, while jointly with the National Physical Laboratory the Station has initiated an investigation into the subject of noise in flats. Of equal importance to the householder from this point of view is some of the work of the research associations such as that of the British Non-Ferrous Metals Research Association the investigations of which have thrown much light on the corrosion in hot water installations in which copper circulating pipes and galvanized tanks are used in the same system. Experimental work on underground corrosion of lead water pipes, cable sheaths, etc., has also been initiated by the same Association, while the British Electrical and Allied Industries Research Association is making important contributions to public safety and comfort by its detailed investigations of fire risks associated with electrical plant, the protection of overhead lines against lightning by more efficient earthing and the properties required in overhead line wires, and the means of eliminating transformer noise. Again, the work of the Research Association of British Rubber Manufacturers on rubber floorings has led to the preparation of an appropriate British Standard Specification which should assist the general public to obtain a satisfactory article.

Other work carried out at the Building Research Station such as that concerned with methods of cleaning stonework with water without hard scrubbing, where a very promising process is now being tried, or on the failure of paints, bears directly on the amenities of buildings, and in this field the Research Association of British Paint, Colour and Varnish Manufacturers is also making important contributions often in direct co-operation with the Building Research Station. Conclusions from work on the preservation of iron and steel by means of paint have recently been consolidated in relation to practical needs.

No less interesting, however, is the work of the Department which touches upon questions of clothing, whether indirectly, as in the investigations of the British Cotton Industry Research Association on the sizing of rayon warps or on the spinning and cleaning of cotton or in those of the Wool Industries Research Association on the problems arising out of the treatment of wool to confer resistance to shrinkage which has led to a new process for reducing shrinkage, or directly, as in the studies of the British Launderers' Research Association on the washing of woollens or the fundamental properties of detergents. Mention can here only be made further of the Wool Industries Research Association's investigations on substitutes for olive oil for oiling wool, prompted by the shortage of supplies consequent upon the Spanish Civil War, and on the use of rubber in conjunction with wool; to that of the Linen Industry Research Association on spinning a new type of linen yarn; and to that of the British Boot, Shoe and Allied Trades Research Association on walking research, in which good progress has already been made in what is really a long range research. A number of interesting side issues are also being explored. For example, the importance of flexibility in the work has led to the development of a flexibility meter for measuring the flexibility of shoes and another machine is being developed to put shoes through the motions of walking and give soles the treatment they receive during wear so as to obtain an insight into the best combinations of materials and constructions to give maximum durability. In addition, the question of occupational footwear has come to the front during the year, and the Association is giving attention to the design and specification of boots and shoes for different occupations.

It is impossible to go into greater detail into the ways in which the Department, whether through the Research Associations or its special Research Stations or Boards, ministers to our daily needs. If the ordinary citizen is perhaps most likely to be interested in motoring as a means of transport, other forms of transport are equally served by the Department. Reference has already been made to research on the transport of food in storage by sea. Even more fundamental contributions to the design of all classes of ships are made in the William Froude Laboratory at the National Physical Laboratory, where a record number of ship designs were tested. Of the 1,180,000 tons of merchant shipping the construction of which was commenced in Great Britain in 1936, 78 per cent was based on tests in this Laboratory. Experimental work on the influence of waves on the resistance, propulsion and pitching of ships is already leading to improvements in design of different types of ship, while in the Aerodynamics Department of the National Physical Laboratory not only are new types of aircraft being tested but also important work bearing on the safety of flight has been carried out.

The National Physical Laboratory renders such significant assistance to the work of so many research associations and Government departments, quite apart from its direct scientific assistance to industry that it forms something of a keystone in the structure or organization of the Department. Nor should it be forgotten that much of the less spectacular work, whether in the collection of and dissemination of information, the testing and establishment of standards is of no less importance than work leading to advances or developments which catch the public eye. Indeed, without the foundation of knowledge thus accumulated and the network of services thus established, it is highly improbable that such advances and the important savings to industry and the community which have accrued from the work of the Department would have been achieved to anything like the same extent. The magnitude of these savings can only be illustrated here by reference to one example. The forty to forty-four per cent improvement in efficiency in steam-generating stations in the last two years is attributed largely to the work of the Electrical Industries Research Association, and on the output of units sold in 1935, the higher efficiency represents a saving in coal of more than £7,000,000. Even only ten per cent of this sum exceeds the total annual expenditure of the Association on all its researches, and it is doubtful whether any other expenditure in the national budget brings in anything like the same return as the £600,000 expended by the Department of Scientific and Industrial Research.

Relics of the Mt. Pelé Eruption of May 8, 1902

By Dr. C. T. Trechmann

THE uncouth and sinister-looking volcano of Mt. Pelé (or La Montagne Pelée) occupies the north end of Martinique and rises to about 4,400 ft. The rest of the island consists of lavas, tuffs and limestones which have yielded a fauna of Miocene, probably of Helvetian age. Mt. Pelé had minor eruptions in 1792 and 1852, but began to give warning near the end of April 1902. The great eruption or *nuée ardente* came at 8 p.m. on May 8, 1902. St. Pierre, the one-time capital of the island, with thirty to forty thousand inhabitants, six miles south of the volcano and just within the triangular zone of destruction, was overwhelmed. Further destructive *nuées* occurred during 1902 and 1903, and they were renewed during 1929 and 1930, when avalanches of incandescent stones, some of them as large as haystacks, were projected down to the sea at the Rivière Blanche.

Perret defines a *nuée ardente* as an "avalanche of an exceedingly dense mass of hot, highly gas-charged and constantly gas-emitting fragmental lava, much of it finely divided, extraordinarily mobile, and practically frictionless, because each particle is separated from its neighbours by a cushion of compressed gas."

The well-known spike or spine of hypersthene andesite which was protruded from the summit first appeared about November 3, 1902, but had fallen to pieces by July 1903. It was grooved on one side through squeezing against the sides of the aperture, and reached a height of 900 ft. An eyewitness at Morne Rouge said there were seven luminous points on the volcano's side just before it burst. This seems to indicate that gases were rapidly melting their way through the side of the cone.

These scorched and melted relics have often been attributed in part to the conflagration that burnt up the town after the eruption, but Perret records that bottles were softened and green mangoes converted to charcoal in places where no conflagration occurred. He also records that barefooted negroes entered the town on the afternoon of the day of the eruption, and photographs show quantities of wood and trees in all parts except those nearest the volcano. Reports of the conflagration are probably exaggerated. The sudden rain of intensely hot ashes would probably immediately drive off or distil a great volume of inflammable gas from the large quantities of rum, oil, wood, sugar, coal, etc., stored in the city and this would ignite immediately in contact with the oxygen outside the erupted gases. The only one of the seventeen ships in the bay that got away was the *Roddam*. Part of her cargo consisted of what appears to be china clay; this has been baked to brick and sprinkled with ash, which has combined with the material to form spots of brown melt.

We may safely conclude, therefore, that it was the direct action of the *nuée* that brought about the curious effects shown by these relics; as it certainly was the cause of the instantaneous death of all the inhabitants—with the possible exception of one survivor in the prison. On a shelf above the entrance of the prison cell, which faces away from the volcano, I found two completely carbonized ship's biscuits. If the prisoner had been equally well baked, there could not have been much life left in him. By some, he is regarded as a negro who had gone in to loot, and got badly burned, and when found made up the story for the benefit of newspaper reporters. It seems likely that no human being in the city survived. One does not like to spoil a good story, but the truth will never be known.

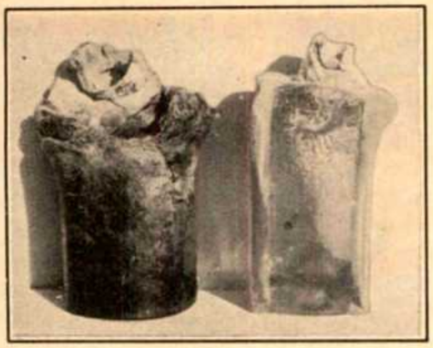

Fig. 1.

BOTTLES PARTLY COLLAPSED AND CONVERTED INTO PSEUDO-WOLLASTONITE. THAT ON THE LEFT HAD CARBONIZED LIQUID IN IT.

It is generally agreed that the erupted gases consisted mainly of superheated steam. Sapper says that hydrogen sulphide and sulphur dioxide were present, with only slight amounts of carbon dioxide and monoxide, but the actual composition and temperature of large-scale eruptions is very difficult to ascertain; 1000° C. may be a good moderate estimate. Bottle glass begins to soften at 670–700° C. Perret has estimated the internal temperature of the crater at not less than 1200° C. The fusion zone in a cement rotary kiln, a bright red heat, is about 1450°–1550° C., and the gases that reached St. Pierre were certainly less than this, but the action so far from the crater seems to have been that of shooting tongues of flame rather than a homogeneous blast. Many objects were not melted or only melted in one part.

Most glass objects are struck and collapsed on one side; lamp shades or bottle necks have been crumpled up while the ash was falling through, and it has been imprisoned in the folds. A bottle tends to split open, but immediately afterwards the ends of the crack are healed up again and the sharp edges are rounded. Ordinary bottle glass is frequently coated with a layer on both sides of fibrous pseudo-wollastonite, beneath which the surface of the glass shows a crackled perlitic-like structure. One can see where the impact of each grain giving off gas has started the devitrification. Bottles that have lain in the hot ashes are reduced to a boiled-up mass of the wollastonite-like material with wisps of unaltered glass here and there (Fig. 1).

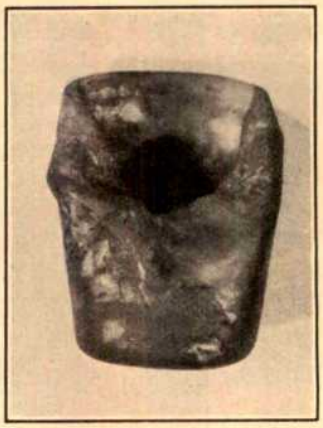

Fig. 2.

A SMALL CUT-GLASS LIQUEUR GLASS. THE EDGES AROUND THE COLLAPSED PART SHOW THE TEKTITE-LIKE GROOVES AND PITTINGS.

Heavy brilliant glass objects such as decanter stoppers, knife rests, etc., are often coated with a dull leaden coloured film which Dr. J. A. Smythe has determined as probably silicates of iron, lead, and copper. Blue copper-silicate glass receives a coating of dark red colour, cuprite or copper oxide among which minute glistening crystals of metallic copper can be seen with a lens.

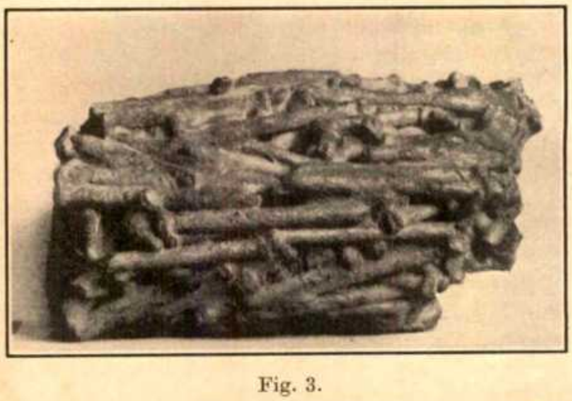

Fig. 3.

A BOX OR BAG OF NAILS CONVERTED TO MAGNETIC OXIDE OF IRON.

Some of these heavy or flint glass objects are eroded with pits or channels or burst bubbles of a very smooth or polished nature suggestive of the structure one sees on tektites or moldavites

(Fig. 2). A decanter stopper completely covered with this darkened film has the knob drawn out sideways and carries grooves resembling those one sees on some meteorites.

Smaller iron objects, nails, wire, locks, etc., are converted to crystalline magnetic oxide, sometimes with a core of metal left (Fig. 3). It seems to be galvanized objects that were most easily oxidized, and around the nails the layer of oxide is sometimes arranged in a spiral form as if the gases had whirled round and completed the oxidation instantaneously. Coins are fused together or become saucer-shaped or are partly melted into blobs or have swollen up, obliterating the design on them; some have a malachite-like coating resembling the patina on ancient coins. A gold Portuguese coin in the St. Pierre museum is merely distorted; gold melts at about 1075° C.

Organic material—biscuits, macaroni, coffee, wafers for religious purposes, etc.—are, when struck by the *nuée*, changed to glistening porous charcoal with little or no loss of outward shape. I have a bottle the upper part of which has been collapsed and 'wollastonitized', but when it was broken open the one-time liquid, which may have been oil, was found to be extremely porous charcoal, but the upper surface was level and intact.

In the St. Pierre Volcano Museum are bottles of perfume with the liquid sealed in them by the sudden impact of the gases. I have a glass door handle which has run like wax, but the part inserted in a silver frame that has been attached to the door is unmelted.

One can still find quantities of human bones in some of the old houses, and these are partly scorched black or partly remain white, indicating the incomplete scorching of the bodies as one sees in photographs. Instead of being burnt off, the flesh and skin seem to have been scorched on to the bones, a sort of mummification process. Hair and clothing are mostly unconsumed; and a box of matches that had not been ignited was found on or near one of these bodies.

These terrible gases, the negation of everything living, were pursuing their natural function of endeavouring to convert everything in their way into igneous material, but their effect must have lasted only a very few minutes.

The effect of such potent gases underground in altering the composition of rocks would bear further inquiry. In Jamaica, in a sea-cliff section below the Lazaretto near Kingston, the Tertiary white limestone has been altered in a peculiar manner. Quite independently of the bedding, the rock grades down into a layer of yellow dolomite, this is succeeded below by a layer 1–2 ft. thick of dense marble, while below this is a dome-like mass of dark splintery material which one can only term hornfels; associated with this or embedded in it are masses of a quartz porphyry. It would seem that gases at a high temperature had come up from below and melted their way into the white limestone. (*Geol. Mag.*, p. 261, June 1936.)

An Historic Mantelpiece at the Royal Institution

By Thomas Martin, General Secretary of the Royal Institution

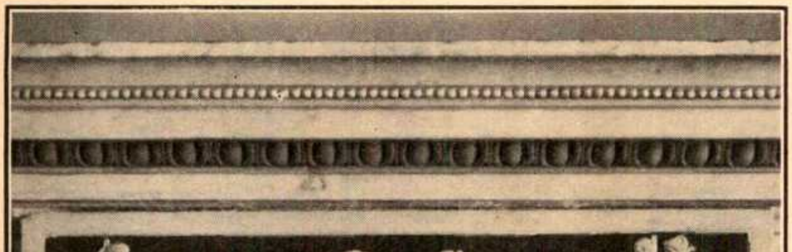
A FINE mantelpiece in the Adam style, an attractive example of the work of the late eighteenth century, has recently been acquired by, and erected in, the Library of the Royal Institution. It comes from the house of the botanist, Sir Joseph Banks, at 32 Soho Square, London, now unfortunately demolished, in which the Institution was founded. It is thus an object of historic interest in its new home. Moreover the recent vicissitudes of the mantelpiece, particularly of the central Wedgwood panel which forms its principal ornament, are not without interest.

When in 1771, Joseph Banks returned to England after his voyage to the South Seas with Captain Cook in the *Endeavour*, he found himself considerably 'lionized'. He, and his scientific associate, the Swedish botanist, Dr. Daniel Solander, were greatly in demand for the tale of wonders they had to tell. They had brought back a magnificent collection of new and strange species of plants and animals from the antipodes and much valuable information as to the natural resources and native races of the lands they had visited. The full story of their adventures may be read in Banks's "Journal"[1] and in Captain Cook's own "Journal" of the voyage[2].

The voyage of the *Endeavour*, which showed Cook to be the first navigator, no less established Banks as the first naturalist of his age. He had contributed liberally, from the fortune he had inherited, to the scientific expenses of the voyage; and he now became a public figure. In 1778, at the early age of thirty-five years, he was elected president of the Royal Society. In the following year he married, and in 1781 was created a baronet.

He needed a town house which would be convenient for his scientific activities and in which his valuable collections and scientific library, with Solander as their curator, could be installed ; and took No. 32 in the south-east corner of Soho Square. The design of this house has been attributed to Robert Adam. Probably the Adam brothers reconstructed it for Banks and added the façade ; but that it was their work has not been definitely established.

The home of Sir Joseph and Lady Banks speedily became a meeting-place for men of science and affairs in London. Her hospitality and his authority brought to their regular gatherings many of the most distinguished men of the day. At one period, according to Sir Henry Holland, who was later president of the Royal Institution, Cavendish, Wollaston, Davies Gilbert, Sir Humphry Davy, Thomas Young and Sir William Herschel frequented their rooms. Even John Dalton, in his Quaker dress, was seen there occasionally[3]. Committees met at the house. No doubt it was due to Banks's infirmity—for he was a martyr to gout, and in his later years could move about only in a wheeled chair—that even meetings on the business of the Royal Society were occasionally held at the President's home.



CENTRAL PANEL IN THE BANKS MANTELPIECE AT THE ROYAL INSTITUTION

The first meeting of Proprietors of the Royal Institution—those who had responded with a subscription of fifty guineas each to the appeal drawn up by Count Rumford and communicated to the public by the Society for Bettering the Condition and Increasing the Comforts of the Poor—was held under Sir Joseph Banks's chairmanship, in his house, on March 7, 1799. It was by the resolutions taken at this meeting that the Institution Rumford had conceived may be said to have been actually formed. Subsequent meetings of the Managers of the new body were held at 32 Soho Square, until the house in Albemarle Street was occupied.

Sir Joseph Banks had had his house specially arranged for the purposes of his scientific meetings and entertaining, as well as for accommodating his collections. In particular, on the first floor, he had constructed a large and lofty room, magnificently decorated, known as the 'council chamber'. The domed ceiling of this room was a triumph of design and the most beautiful decorative feature of the house. On the same floor was another smaller room, the drawing-room.

When, before the demolition of the house in 1937 (see NATURE, **139**, 280 ; 1937), the decorative fittings it still contained were sold by auction, the mantelpieces from the council chamber and the drawing-room were, by the generosity of Sir Robert Hadfield, purchased and presented, the former to the Royal Institution, the latter to the Royal Society.

The mantelpiece from the council chamber was found to have, as its central ornament, a white marble panel of a reclining nymph. It happens that *Country Life* had published, on September 27, 1913, a description of 32 Soho Square as it then was, including a photograph and description of this mantelpiece. The central panel was of different design, described as "a Wedgwood in green and white". It was obvious that the original had been removed and replaced by another.

It was disappointing to find that the mantelpiece was not now as it had been in Banks's lifetime, and efforts were made, without much hope of success, to trace the original panel. It was found, on inquiry, that in 1914, when the house was empty for a period, thieves broke in and stole the Wedgwood panel. They also loosened the whole mantelpiece preparatory to removing it on the following night, but were prevented, and left it undamaged.

Failing the original, it was hoped to obtain a replica of the panel. The help of Dr. John Thomas, of Stoke-on-Trent, who has made a study of the early Wedgwood designs, was solicited and generously given. Thanks to the willing co-operation of the directors of Josiah Wedgwood and Sons, Ltd., Dr. Thomas, who devoted much time and skill to the problem, was completely successful in tracing the history of the panel. He was provided with an enlargement from the *Country Life* photograph, and concluded, from a comparison of this with other designs, that the panel, which was of a 'sacrifice' type popular in the eighteenth century, was most probably made to the special order of Sir Joseph Banks by Josiah Wedgwood. It was a composite design of white jasper figures against a green, instead of the more common blue, background, composed of six separate groups worked up into one theme or ensemble representing a sacrifice to Flora. For each of the groups, consisting of vestal figures carrying offerings, and Bacchanalian boys, a separate mould had been used, and the six, when assembled, composed a tablet about 1 ft. 9 in. wide and 7½ in. high. The design may be taken to symbolize Banks's interest in flowers and his pursuits as a botanist.

Dr. Thomas crowned his success by discovering, after a search in the dusty mould rooms of Messrs. Josiah Wedgwood and Sons, the actual moulds which had been used for the tablet. From these, the firm undertook to prepare new working moulds and attempt the manufacture of a replica.

All hope of recovering the original had been abandoned, and the order for the replica had actually been given, when information was received from a firm of dealers in London, of whom inquiry had previously been made, of a panel which had come into their possession, which they believed to be the missing one. It was taken to the Royal Institution and closely compared with the photograph. It corresponded in every detail. It must be either the original or a duplicate made at the same time. It was compared for shape and size with the recess left in the stonework of the mantelpiece to receive it. It fitted exactly. There could be no reasonable doubt that it was the original.

Thus the panel, a beautiful original specimen of Josiah Wedgwood's art and in excellent preservation, as the accompanying figure shows, is restored to its rightful position after a lapse of twenty-four years, and the mantelpiece, complete as it stood in Sir Joseph Banks's council chamber on the day the Royal Institution was founded, finds a new and appropriate setting in the Institution's house in Albemarle Street.

Obituary Notice

Dr. C. Lallemand

Dr. Charles Lallemand died on February 1 at his country house in Bussy par Joinville (Haute-Marne), after a long and painful illness, in his eighty-first year. Few men of science of modern times have left a wider international reputation behind them, and fewer still so clear and definite a personal impression.

Lallemand was early in showing his marked ability. At seventeen years of age he was admitted to the Ecole polytechnique, from which he was posted to the Corps des Mines, and passed out first among his contemporaries. It is remarkable that he should have started at once on his final career, and should have done so as chief of his own department. He was immediately appointed secretary to the inter-departmental committee then sitting to discuss the formation, and terms of reference, of a department to undertake the first-order levelling of France. The circumstances of that time may be briefly recalled.

France had then no national levelling department, nor was the Service Géographique de l'Armée (responsible for the triangulation) charged with its execution. Twenty years after Prof. Whewell's levelling from the English to the Bristol Channels, and only two years before the Ordnance Survey was to complete the first-order levelling of Great Britain, the French Ministry of Public Works appointed that eminent geodesist, Bourdaloué, to level the main roads and canals of France (1857). His network of 15,000 kilometres was finished in 1864, but he left behind him no permanent arrangements for extension or upkeep. In 1878 an ambitious project of public works called for levelling much more general in extent, of a higher precision, and so continuous in policy and maintenance as to necessitate a responsible and permanent department.

The inter-departmental committee, of which mention has been made, was formed, sat for six years, and reported in 1884. As a consequence, the Service du Nivellement was inaugurated, and Lallemand, who had won the confidence and esteem of all his colleagues, was made director at the age of twenty-seven years. Much of the preliminary work he had already done. He had outlined, in detail, the methods to be followed, and the routine of computation. On his appointment as director, his first duty was to modernize, and indeed practically to re-design, French geodetic levelling instruments and staves. He perfected and introduced many semigraphic solutions for the computation of corrections of the minor orders, and his formulæ for the classification (in precision) of levelling nets were adopted (internationally) in 1912. His administrative and executive measures were as successful as his technical. The programme, as originally outlined, was to last for ten years and to include some 800,000 kilometres of circuits. There have, however, been many financial difficulties, and Lallemand has not lived to see its completion. Some idea of the precision of his first order may be gained from the final misclosure of 50 centimetres in his 4,000-kilometre circuit of France (1/8 M.). It is claimed for his administration that it reduced errors to a third of those prevalent in Bourdaloué's net, whilst it greatly reduced expense.

In 1898, Lallemand was called upon to reorganize the cadastral survey of France. The old communal system, originally introduced by Napoleon, rested merely upon chained triangles. The 1/2500 *parcellaires*, or property plans, had more in common with our tithe surveys than with the reliable Ordnance plans, and it fell to Lallemand to introduce a dependence on the triangulation of the Service Geographique, to advocate contouring, and generally to modernize a none too efficient regime.

It was a bitter disappointment to Lallemand, and a serious loss to France, when credits were cut off, and the cadastral survey was allowed to fall back into decay in 1907.

In 1910, Lallemand was elected a member of the Academy of Sciences, and in 1917 a member of the Bureau des Longitudes. Of both these bodies he was eventually to become president. In 1914, it may be said that Lallemand was as unquestionably the authority on levelling as was Helmert in geodesy generally.

In 1919, therefore, Lallemand, collaborating with the founders of the International Research Council, brought with him the reputation of first-class geodetic ability combined with proved administrative success. He was chosen, unanimously, president of the International Union of Geodesy and Geophysics, and it is in that connexion that he is best known in international circles to-day. He retained that position for fourteen years, and his great personal and scientific abilities made him a magnificent success. He was an astonishing linguist. At Rome, Madrid, Prague, Stockholm and Lisbon his presidential addresses were given largely in the languages of the countries concerned. As one would expect from so strong and able a man, he had his differences with his colleagues. Yet none who may have differed from him in detail would fail to pay the warmest tribute to the dignity, charm, scientific eminence and administrative ability which he put, whole-heartedly, at the service of international science. The Union of Geodesy and Geophysics, cherishing his memory with affection and admiration, knows that it owes to him much of its present position.

H. St. J. L. W.

News and Views

The Scientific Delegation to India

THE Council of the British Association has forwarded the following resolution to the Indian Science Congress Association and to Government authorities, institutions and individuals who helped to make possible the recent visit of the Scientific Delegation to India: "The Council of the British Association have learned with gratification of the complete success that attended the visit of the Scientific Delegation to India, the members of which through the invitation of the Indian Science Congress Association, were enabled to co-operate in its Jubilee Meeting in Calcutta, to visit many places of scientific and historical interest in India, to become acquainted with the work of many universities and other institutions, and to make or renew personal contacts with large numbers of Indian scientific workers and leaders of thought. The Council are glad to hear of the opinion, widely expressed in India, that much good would result from the visit, and this belief the Council heartily reciprocate. The Council desire to endorse the expressions of gratitude which have already been transmitted on behalf of the Delegation, to the Government of India, to all other participant authorities and individuals, and very specially to the executive of the Indian Science Congress Association."

Rearmament and Research: Comparative Costs

IN a White Paper issued in February 1937, it was estimated that Great Britain's total expenditure on defence during the five financial years 1937–41 would be £1,500,000,000; the estimate for 1937 was £278,250,000. According to the "Statement Relating to Defence" issued by the Government last week, the estimate for the present year is £343,250,000, and £8,500,000 is provided for air raid precautions services alone. Further, it is stated that the expenditure in 1939 is likely to be even greater, and that the total cost of the five years' rearmament will probably exceed the original estimate made in 1937. The Statement gives in general terms an outline of the ways in which the money is being spent and of the progress of the rearmament schemes on which Great Britain has embarked. This document will be read with mixed feelings, among them being dismay that the international situation should, in the opinion of responsible men, require the expenditure of such vast sums on armaments and defence. One cannot help contrasting this enormous outlay with the amount spent annually on scientific research, any item of which may eventually prove of outstanding worth. Elsewhere in this issue (p. 432) is an article on the work done during 1936–37 through the Department of Scientific and Industrial Research, based on its latest report. From the report, it will be seen that, for the very modest expenditure of £600,000 during the year, investigations on food, clothing, housing, transport, etc., have produced results of general value to the health, happiness and economic well-being of man. It is a sad commentary on the state of civilization that, as a result of national animosities, the Government of a leading State and world power should spend in one year some five hundred times as much on armaments and defence as on potentially productive scientific investigations.

Marble Mantelpieces from Banks's House

BESIDES being for thirty-six years (1821–1857), the home of the Linnean Society, No. 32 Soho Square, London, which was demolished in 1937 (NATURE, 139, 280; 1937) was historically connected with both the Royal Society and the Royal Institution. From 1777 until his death in 1820, it was the town house of Sir Joseph Banks. Traditionally, Council meetings of the Royal Society were held there, and although this has not been confirmed, there can be no doubt that, during Sir Joseph Banks's long presidency, meetings on the business of the Society were held at the President's home. The Royal Institution was founded there at a meeting held under Sir Joseph's chairmanship in March 1799. Before it was demolished, the decorative fittings of the house were sold by auction. Two marble mantelpieces were purchased at the sale and presented by Sir Robert Hadfield, one to the Royal Society and the other to the Royal Institution. That given to the Royal Society is to be placed in the Officers' Room of the Society's apartments in Burlington House in due course. The other, it was reported to the members of the Royal Institution at the General Monthly Meeting on March 7, has now been re-erected in the Library of the Institution. An account of No. 32 Soho Square, and of the mantelpiece at the Royal Institution, which has had a most interesting history, is given on p. 437 of this issue.

The Milk Problem in Great Britain

LIEUT.-COLONEL C. WALEY COHEN, in an article in the February issue of the *Nineteenth Century and After*, surveys and discusses the problem of the milk supply in Great Britain. He points out that the milk supply of England and Wales has been reviewed by no fewer than five Royal Commissions and Committees during the last twenty years, and has been the subject of several departmental orders and of legislation during the same period. All this has rendered the farmers nervous and the public bewildered, with the result that the consumption of liquid milk in Great Britain is low, and the price high, as compared with some other countries. A change has also taken place in the method of distribution and supply, for prior to 1900 supply of liquid milk to the consumer was mainly direct, by 1923 producer-retailers supplied only 40 per cent, and to-day only 20 per cent, of the total requirements, the remainder being bulked, often conveyed long distances, and then distributed. Bulking of liquid milk is the key to many of the difficulties surrounding the milk supply: it gives rise to the major problem of milk-borne diseases, and was the proximate cause of the necessity for, and creation of, the Milk Marketing Board. The Great War also created an impetus to the importation of cream, butter, cheese and other milk products from the Dominions and foreign countries.

BULKING of milk largely increases the danger from milk-borne diseases, for a small addition of infected milk will infect the whole of the milk to which it has been added, amounting, perhaps, to 2,000 gallons or more. This, together with the time that elapses between the milk leaving the producer and reaching the consumer, renders some form of heat treatment necessary. In the case of bulked milks, efficient pasteurization is therefore desirable, and a scientific system of pasteurization should be enforced. The risk of milk-borne disease in rural, and in less congested urban, areas is low, as bulking is rare. Efficient pasteurization in small urban, and in rural, areas is expensive, and would deprive these areas of the reduction of 4*d*.–6*d*. per gallon in retail milk price which they now enjoy. The grading of milk, and the accredited scheme, receive some criticism. Colonel Cohen desires the establishment of some better 'concordia' on the medical side between experts, practitioners, medical officers of health, bacteriologists and veterinarians; on the commercial side between producers, distributors and manufacturers; and generally between all these and administrative officials. Nothing should be done to restrict or discourage the production of milk in Great Britain, for the industry is outstanding in the agricultural economy of the country, and the income from milk and dairy produce forms no less than 28 per cent of the nation's agricultural income. Finally, it is suggested that there is much scope for the establishment of a permanent Milk Commission, with a real administrative competence.

Films and Folk-Lore

IT is remarkable that little use has been made in Great Britain of the cinematograph for recording systematically the survivals, now rapidly diminishing in number, of customs and festivals formerly observed among the people. British anthropologists were not slow to appreciate the possibilities of the cinematograph in field work: and more than thirty years ago the Daniels-Seligman anthropological expedition to New Guinea secured some striking records, as also did the late Sir Baldwin Spencer in the Northern Territory of Australia in an illuminating series of films of native ceremonial dances shown in London in 1914. In the home-field, however, notwithstanding more favourable conditions, this potential auxiliary of scientific study of folk-custom has been sadly neglected, although the commercial film has shown appreciation of the spectacular value of brief episodes of folk-dance and ceremonial for the news-reel. Familiar as these were, the value to the student of the film taken for purposes of scientific record only, and not as part of a public performance, was brought out by some of the Continental films, especially the instrumental films, shown at the International Folk-Dance Festival in London in 1935, which came as something of a revelation. It is satisfactory to note, therefore, that an attempt is to be made to remedy the deficiency in the equipment of folk-lore studies in Great Britain by an endeavour to secure a record of folk survivals, which will include not only folk-dances and folk-customs, but also folk-crafts, which are in danger of extinction. The proposal, it is announced in a communication to *The Times* of March 7, is put forward on behalf of the Folklore Society, the English Folk-Dance and Song Society and the National Film Library. Sound films, it is also suggested, might be made of such activities as the almost extinct art of hand-bell ringing and of folk-dances *in situ*. The expense of carrying out such a scheme obviously will be considerable, and it is hoped that private benefaction will be forthcoming. In view, however, of the scientific and historical interest of local custom, whether ceremonial or industrial, the local museum, especially where an attempt is made to illustrate local antiquity and history at all adequately, might regard a subsidy in aid of a local film as a legitimate charge on its financial resources.

The New Commonwealth

THE eighth in the series of broadcast talks on "The Way of Peace" was given on March 3 by Lord Davies, who spoke on the New Commonwealth. This is, he said, a voluntary, international society, composed of members living in forty-six different countries, who have banded themselves together in order to enlist the support of public opinion for the establishment of two institutions—an equity tribunal or commission, and an international police force—as part of the permanent machinery of the League of Nations. No Government could carry on for a single week unless it possessed institutions capable of effecting changes in its laws, and the means of upholding them. How then can we expect the League to inaugurate the rule of law if its members refuse to give it those institutions essential for carrying out the responsibilities they have entrusted to it ? War can only be prevented by establishing international law and order on the same principles, and by the same methods, which have been successfully applied in the development of every civilized community. Lord Davies then dealt briefly with the two institutions in the New Commonwealth programme. The task of the equity tribunal would be to deal with any disputes which the League Council fail to settle by the existing procedure of negotiation and conciliation. The aim of the second point of the New Commonwealth programme, said Lord Davies, is the substitution of co-operative for competitive armaments. This can best be done by means of a police force under the control of the international authority. Only in this way, he considers, can the rule of law be established and the downfall of Western civilization averted.

Gliding and Soaring Flight

AT the Friday evening discourse at the Royal Institution on March 4, Prof. D. Brunt discussed "Gliding and Soaring Flight". As the modern sailplane has a sinking speed in still air of 2–3 ft. per second, it will soar in an ascending current which rises faster than this modest limit. Three types of ascending currents occur in the atmosphere. Where the wind blows against the slope of a hill, it follows the contour of the ground, and if the air rises faster than the sinking speed of the sailplane, the latter can soar over the hill slope. Such a flight of 9 hours 48 minutes was carried out at the international competitions in Germany last summer, by Messrs. Fox and Murray in a Falcon III two-seater. When the air near the ground is heated until the rate of fall of temperature with height exceeds 5·6° F. per 1,000 ft., the air becomes unstable, and currents of warm air rise, and, if damp, give rise to clouds. Under the cumulus clouds then formed, the sailplane can mount in the rising air. When the wind increases with height the clouds are in long rolls, which have ascending air under their whole length, and in this air the sailplane can soar along the whole length of the cloud. In the rear of a depression, at the cold front, where the cold air pushes under warm air and forces it to rise, the rate of ascent of the warm air is often sufficient to enable a sailplane to soar. The British record for distance of soaring flight is 104 miles and was set up by Mr. Philip Wills. The world's record for distance, 405 miles, was set up by a Russian pilot in May, 1937.

Asymmetric Sideband Broadcasting

MR. P. P. ECKERSLEY in a paper read to the Institution of Electrical Engineers on March 2 said that the present methods of working permit few, except local radio broadcasting stations to be received without interference from other transmitters operating in contiguous frequency channels, unless the upper frequencies of modulation of the wanted station are severely attenuated. In this case the reproduction lacks intelligibility and naturalness. This can be mitigated without introducing audible harmonic distortion by utilizing the asymmetric sideband system of transmission to cut away with the aid of electrical filter circuits part of one sideband of the frequency spectrum radiated. In a previous paper, the author has shown how 'asymmetry', either of phase or of magnitude, between two sideband components is related to harmonic distortion. It is proportional to depth of modulation. He proved that as the sideband frequency becomes more and more removed from the carrier frequency, it may be more and more attenuated while the distortion can be made to remain constant and small. The author suggests that it is better to face the occasional minute deteriorations in quality given by the asymmetric system than to suffer from the continuous hissing and splitting sounds brought about by existing inter-station interference. The public insists that the radio-set exists to give pleasure. The attention that a user gives to a programme is determined partly by the quality of reproduction, but probably more by the freedom it enjoys from interference from extraneous sounds. It is primarily programme interest which pleases, but interference is very objectionable however good the programme. The author acknowledges his thanks to the B.B.C. for providing the funds for the construction of test apparatus. He also thanks the Countess von Zeppelin for her mathematical investigation, given in an appendix, resulting in a most useful expression for the distortion component.

Reclamation of Tidal Lands

IN a lecture delivered before the Royal Society of Arts on February 23, Mr. Oscar Borer described the process of land reclamation work as applied to the coastal frontages on both sides of the North Sea, tracing the origin of such operations to the time of the Romans under whose direction a bank was constructed across the Wash at some date prior to A.D. 359, and when other embankments were made between Lincoln and Norwich, aggregating not less than 50 miles in length and having a height of 10 feet. After the cessation of the Roman occupation, very little additional protection seems to have been undertaken along the British coastline until the seventeenth century, when during the reign of James I and afterwards, large tracts of marshlands, amounting to 35,000 acres, were excluded from tidal influence. During the eighteenth and nineteenth centuries, other areas approximating to 10,000 acres were reclaimed. Of the total quantity enclosed since Roman times, 8,000 acres was marshland in Norfolk along a frontage of ten miles, and 37,000 acres in the South Holland district of Lincolnshire with a frontage of nineteen miles, the remainder being in the North Holland district. In the Netherlands, from Roman times until the beginning of the fifteenth century, extensive areas were lost to cultivation through floods, the surface level of the land having sunk so that it was easily invaded. Early dikes made to offer defence against the sea broke down, and in this way the Dollart was formed in the twelfth or thirteenth century. The Zuider Zee, which had once been largely dry land, was inundated about the same time. The largest 'polder' recently reclaimed in this area is the Wieringermeer, in the north-west corner. It has an area of 48,000 acres and was dried in 1930. A second enclosure in the north-east corner was started in 1936, and it is expected that in due course another 110,000 acres will be available for agriculture. On the German North Sea coast, 8,000 acres has been embanked since 1900 in the province of Schleswig-Holstein.

The Disappearing Fauna of Africa

THE problem of the disappearing fauna of Africa formed the subject of a lecture before the University of London Animal Welfare Society on March 7. It has been common knowledge for years that the status of many of the big African animals was precarious. The last quagga died in 1882, and the three big pachyderms have been killed off at an alarming rate. Not only are the indigenous beasts being wiped out under the 'protecting' eye of a white civilization, but also the majority of many species are dying unnecessarily cruel deaths at the hands of the African native, working with old-fashioned guns and pitfalls and traps. Possibly only a few thousand gorillas remain alive to-day, in the Cameroons, where they are exploited by man, and in the Parc National Albert, where they are protected by the Belgian Government. The elephant has disappeared from most of its old haunts. In the three British dependencies a minimum of 6,000 a year are killed, chiefly in the 'control campaign'. Tanganyika and the lake swamps are the last haunts of the hippopotamus, and unless help is forthcoming this will eventually disappear. On November 8, 1933, the London Convention for the Protection of the African Fauna and Flora was signed. The first of a series of subsequent international conferences should have taken place before November 1937. No conference has been held, the reason given being that the British Government intends to summon a conference on tropical Asia and the western Pacific, certain of the experts interested in those regions being also interested in Africa. At the meeting, the Society passed a resolution calling upon the Government to take urgent steps for summoning the London Convention for the Protection of the African Fauna promised for November 1937.

Locust Outbreaks in Africa and Western Asia

THE recent report of the Committee on Locust Control is the sixth of its kind which deals with locust outbreaks in the regions mentioned. In the present instance it covers the year 1936 and the early part of 1937, and has been prepared by Dr. B. P. Uvarov and Miss W. Milnthorpe. The report is a survey of the conditions in the territory named and is based upon the accumulated data which has come to hand as the result of international organization. It appears that the general situation, in so far as the African migratory locust and the red locust are concerned, is steadily improving. Particular stress, however, is laid on the beginning of a new outbreak of the desert locust which has been definitely proved to be forming in the Sudanese-Arabian area. It has been due to the regular system which is operating for the recording and collection of all data relating to locusts, and its centralization in a single institution (the Imperial Institute of Entomology), that the first signs of this outbreak have been recognized and warnings issued to all countries likely to be affected by the locust in question. The concerted measures which are being undertaken in order to endeavour to fathom the causes of locust outbreaks merit every support. The elaborate organization which has been built up and got into working order at the prime instigation of Dr. Uvarov provides the only sound method of attack—mere remedial measures are temporary palliatives and leave the locust menace unimpaired. At the present stage of the work, no effort should be relaxed, and it is up to the countries directly interested to see that the necessary funds are maintained. The report is available, price 3*s*. net, and is published by H.M. Stationery Office.

Chronica Botanica

THE first re-organized number of *Chronica Botanica* (4, No. 1, February 1938. *Chronica Botanica* Co., P.O. Box 8, Leyden) has recently been issued. This international journal, which deals with all branches of botany, horticulture, agronomy and silviculture, is now bimonthly, and the annual subscription has been reduced from fifteen to seven guilders. Most of the contributions are in English. The present number opens with a short account of the new Association for the Study of Systematics in Relation to General Biology (see also NATURE, 140, 163; 1937) by W. B. Turrill. Sixteen pages are devoted to correspondence and eleven pages to discussions. Notes from contributions of botanical interest to other journals occupy five pages. The reports of recent international congresses and announcements of forthcoming congresses are full and informative. Of outstanding interest is the section of news of more general interest from botanical and related institutes throughout the world. In fact, this section is, so far as we know, unique, and should prove of inestimable value to botanists, especially those engaged in research. The obituary announcements and notices are very full, and several portraits are included. Similarly, recent appointments and resignations are announced. This journal has achieved a world-wide reputation in a very short time. For this, the editor (Dr. F. Verdoorn) is to be congratulated; but it is well deserved. He and his advisory editors must be indefatigable in their efforts to glean botanical information from all parts of the world, resulting in a journal of plant science which all interested in plants will find of absorbing interest and great utility.

The *Tree Lover*

THE editorial in the *Tree Lover* (vol. 2, No. 21; 1937) deals with several points in connexion with trees and forestry principles in the opening words "More and more do Trees become 'news' and the claims of forestry find mention in the Press". This is a position which NATURE realized more than a decade ago and has since kept in close touch with this important subject with the object of educating a public who had completely lost all 'forest sense'. The editor perforce alludes to the appalling dust bowls in process of creation in the United States and Canada. But he is equally concerned over the threatened final demolition of Milton's Elm, 500 years in age, at Chalfont St. Giles, the remaining 12-foot stump being in danger owing to the expressed intention of widening the road. As the editor states, "The crisis of Milton's Elm is typical of what is happening all over the Country. One can only hope that ere long there will be a reaction from the ruthless cult of speed". He mentions the several bodies who are taking up the campaign against the increasing vandalism of the builder and road-maker. This autumn quarterly number deals with such matters as Gloucestershire woodlands, Whiligh and its trees, evolution of the moor, and the Royal Gardens of Sandringham and Windsor.

Medical Research in South Africa

THE annual report for 1936 of the South African Institute for Medical Research, Johannesburg, of which Sir Spencer Lister is director, gives an account of the routine and research work pursued there. The bacteriology and epidemiology of pneumonia in local mine natives are continuously studied by Dr. Ordman. The use of prophylactic pneumonia vaccine is increasing in the mines, and a number of satisfactory results continue to be recorded. Routine specimens examined for plague infection numbered 144 from human sources and 1,908 from animals, positive results being obtained in 49 human cases and in 5 rodents. Strains of the plague bacillus maintained in the laboratory have been found by Dr. Pirie to undergo a steady diminution in virulence. Much work has been done by Dr. Mavrogordato upon mine dust and its relation to silicosis in miners' lungs, and Mr. Rabson has determined the size of the particles present in the dust. Ninety per cent of the mass of dust is found to consist of particles of 4µ and less. Malaria research and the prevalence and species of mosquitos in certain districts, the venoms of snakes, and researches on tumour agents, are some of the other subjects that have been investigated.

The Management Library

THE Management Library which was opened to general use by industry in June 1932 has issued a report on progress in the five years ended June 30, 1937. 1,000–1,500 books are now out on loan at a time, or a total of 15,000 volumes in the year, and 1,250 copies of the monthly review are issued to members, subscribers to which come from France, Belgium, Holland, Switzerland, Sweden, Norway, India, Japan and elsewhere. The reviews are now framed to outline the chapter headings, evaluate new contributions to knowledge and to indicate the departments or persons in industry to whom the book is of special value. Although serving various institutions and associations, the Library has no direct affiliation with any other organization. Income from subscriptions has grown from £150 in the first six months to £1,000 in 1936 and £684 in the first six months of 1937.

Education in the U.S.S.R.

ACCORDING to the Soviet Union Year Book Press Service the educational services budget this year shows an increase of more than thirty per cent compared with that of last year (13,916 million roubles), and 3,613 new schools are to be built to provide accommodation for more than a million pupils, namely, 663,740 in rural areas, 518,950 in urban areas, and 35,000 children of railway workers scattered throughout the country. Special schools for railway workers' children already accommodate more than a million. The total urban schools attendance is 8,800,000, the rural schools 21,200,000. The accommodation to be provided by the new schools will therefore increase the capacity of the present urban schools by 6 per cent and that of the other schools by 3 per cent.

Pascal and Seventeenth-Century Physics

The Physical Treatises of Pascal

The Equilibrium of Liquids and The Weight of the Mass of the Air. Translated by I. H. B. and A. G. H. Spiers, with Introduction and Notes by Frederick Barry. (Records of Civilization: Sources and Studies, edited under the auspices of the Department of History, Columbia University, No. 28.) Pp. xxviii+181. (New York: Columbia University Press; London: Oxford University Press, 1937.) 16*s*. 6*d*. net.

THIS volume is a welcome and notable addition to the series entitled "Records of Civilization" published by the Columbia University Press. For the most part, the preceding volumes have concerned themselves with history-sources of very varied range and outstanding interest; in this, the twenty-eighth volume of the series, the editors have adventured upon a notable story in the history of science, and have performed their task in such a way that a reader who has 'preferences but no exclusions' will not readily exchange this volume even for the 'History of Yaballaha III'.

The title of this study is self-explanatory, and the editors have exercised a wise discretion in choosing for this first experiment a story which can be rounded off in comparatively small compass. Here we have, for example, in the space of about two hundred pages, not only the treatises on the equilibrium of liquids and on the weight of the mass of the air, and the "Story of the great Experiment . . . devised by Monsieur B. Pascal . . . and carried out by Monsieur F. P. on one of the highest mountains in the Auvergne, commonly known as Le Puy de Dôme", but also a series of records of certain barometric observations made simultaneously in Clermont, Paris and Stockholm, and an account of "New Experiments, made in England . . ." Following these come three carefully selected appendices. The first is a translation of the relevant portions of Stevinus's work on statics, wherein, following a delightfully formal set of carefully arranged definitions and postulates, one finds the theorems of elementary hydrostatics developed in a series of graduated propositions such as "A solid body *minugrave* to the water in which it lies is equiponderant to the water of which it takes the place". A second appendix gives a translation of Galileo's "Remarks on Nature's Abhorrence of a Vacuum", and a third gives a translation of the text of Torricelli's letter of June 11, 1644, to Ricci on the pressure of the atmosphere, an excerpt from Ricci's answer (". . . it seems . . . that one could exclude the action of the air . . . on the . . . surface of the quicksilver in the basin by placing on this vessel a cover . . . The air above the basin would . . . gravitate no longer on the surface of the quicksilver, but upon the cover; and if then the quicksilver remains suspended . . . the effect could no longer be attributed to the weight of the air . . . ."), and Torricelli's reply of June 28.

It seems, then, that the reader is provided with much of the material which will give him the background of the contemporary outlook and achievements which is so necessary in order to appreciate completely the magnitude and importance of Pascal's contribution to the advancement of knowledge in this particular region.

It is a privilege to have the opportunity of following Pascal's method in general hydrostatics, but the work on the weight of the air leads to a climax of surpassing interest, though, truth to say, it would seem that the worthy Monsieur Perier's contribution to the Puy de Dôme experiment has scarcely received the consideration which it merits. Perier, Pascal's brother-in-law, was "His Majesty's Councillor in the Court of Aids of Clermont-Ferrand", and to him Pascal wrote the letter dated November 15, 1647, in which he suggests that a barometer shall be set up "several times over in one day, with the same tube and with the same quicksilver, sometimes at the base and sometimes at the summit of a mountain at least five or six hundred fathoms high". He remarks that a fall in the barometric height will be decisive, "for it is quite certain that there is much more air that presses on the foot of the mountain than there is on its summit, and one cannot well say that nature abhors a vacuum more at the foot of the mountain than at its summit"; and he remarks further, "I say nothing about the means of performing the experiment, because I well know that you will omit none of the precautions necessary to carry it out with precision".

Perier certainly omitted nothing. He prepares basins and two glass tubes, sealed at one end, and each four feet long. He rectifies six pounds of quicksilver, and at eight o'clock of the morning of September 19, 1648, he proceeds to the garden of the Minim Fathers, where he sets up his two tubes side by side in the same vessel, and remarks that each records a barometric height of twenty-six inches and three and a half lines. He repeats the experiment twice, and sets up one of the tubes in the garden for 'continuous observation', requesting the Reverend Father Chastin, "a man as pious as he is capable, and one who reasons very well upon these matters, to be so good as to observe from time to time all day any changes that might occur". He then proceeds, accompanied by a miscellaneous assemblage of clerics, lawyers, and one general practitioner, to the summit of the Puy de Dôme. Here he repeats the 'vacuum experiment' and finds a barometric height of twenty-three inches and two lines.

Apparently the emotions engendered by a successful seventeenth-century experiment on the spring and the weight of the air find similar, if more vigorous, expression in France as in England, for the whole company is carried away with wonder, delight and surprise. He repeats the experiment six times in all, "once in the shelter of the little chapel that stands there, once in the open, once shielded from the wind, once in the wind, once in fine weather, once in the rain and fog which visited us occasionally". In all these experiments he finds the same barometric height—twenty-three inches and two lines. (It is to be remembered, that between each of these experiments, the apparatus is dismantled, and the tube refilled.) During the descent, the experiment is carried out thrice at an intermediate station, and yields a height of twenty-five inches. On returning to the Minims, he finds that the barometric height has there remained constant at twenty-six inches three lines and a half. He repeats the observation with the Puy de Dôme tube, first immersing it in the vessel in which the tube for the 'continuous experiment' was standing, and then in the vessel which had been carried up the mountain. In every instance the observed height was twenty-six inches, three lines and a half. The whole story affords an admirable illustration of a carefully controlled experiment and it detracts nothing from the originality of Pascal to say that Perier's attendant bark should certainly "pursue the triumph and partake the gale" of Pascal's immortal achievement.

The book is not over-annotated; it has a useful bibliography, and the production is excellent. It is to be hoped that the volume will be the precursor of many others devoted to the history of science—a proportion of one in twenty-eight scarcely expresses the relative importance of science in the records of civilization.

A. F.

Is the Universe Expanding?

The Observational Approach to Cosmology
By Edwin Hubble. Pp. viii + 68 + 7 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 6*s*. net.

THE present volume contains the Rhodes Memorial Lectures delivered at Oxford in the autumn of 1936, and is a sequel to "The Realm of the Nebulæ" based on the Silliman Lectures of the autumn of 1935. The earlier book was a record of what Dr. Hubble describes as a rapid reconnaissance of the extra-galactic nebulæ; the book under review presents, one year later, the results of a much more detailed and thorough observational survey, representing possibly the extreme limits attainable by the 100-in. telescope of Mount Wilson Observatory.

In the earlier book, there was expressed a guarded doubt of the current interpretation of the observations as evidence of the expansion of the universe; in the new volume this doubt is magnified into the central theme. The position can be described quite simply.

The observations are two-fold in character—photometric and spectroscopic. The former lead to estimates of the distances of the nebulæ; the latter give the red-shifts of the observable spectrum lines. If the red-shifts are *not* velocity-displacements due to the recession of the nebulæ in the line of sight, the distribution of nebulæ is inferred to be essentially uniform and the universe to be unlimited in extent. Moreover, with this original assumption the observations show that the red-shifts are simply proportional to the nebular distances, and this law of red-shifts implies a hitherto unexplained principle of Nature, namely, that the energy of a light quantum diminishes with the distance traversed.

On the other hand, if the red-shifts *are* true velocity displacements, the law of the red-shifts is no longer linear and the resulting picture of the universe reveals disturbing features as to its comparatively small scale both in time and space.

The formulæ in the two cases are respectively

$$d\lambda/\lambda = ar \quad . \; . \; . \; . \; (1)$$
$$d\lambda/\lambda = br + cr^2 \quad . \; . \; . \; (2)$$

where $d\lambda$ is the observed displacement for a wave-length λ, r is the distance of a nebula and a, b and c are constants obtainable from the observations. It might be expected that a direct test of the two hypotheses could be furnished by the observations, for, of two identical nebulæ at the same distance from us, one stationary and the other receding with a high velocity, the latter should appear the fainter. But apparent luminosity is, at present, the only practicable criterion for deriving the distances of the very remote nebulæ and so this direct test cannot be applied.

Now, irrespective of the interpretation assigned to the red-shifts, the apparent luminosity of a nebula is diminished as a result of the quantum relation, $E\lambda$ equals a constant, in which E denotes the energy of a quantum which leaves the nebula with wave-length λ and is observed as of wave-length $\lambda + d\lambda$. As a consequence of this relation, it is shown that the apparent photographic magnitude of a nebula is increased by dm, where dm is equal to $3d\lambda/\lambda$. If, in addition, the red-shift is interpreted as a velocity-displacement, the value of dm is increased to $4d\lambda/\lambda$. Making these corrections in succession to the observed photographic magnitudes of nine clusters of nebulæ, Hubble arrived at the formulæ (1) and (2) with evaluations of the coefficients a, b and c. The feature of (2) which we notice is that the coefficient c is found to be positive. This implies that the 'age of the universe' is considerably smaller than that derivable from the linear law (1). From the numerical value of c, Hubble suggests that the maximum permissible span is about 1,500 million years, and that the true value may be anywhere between this maximum and half of it, that is to say, less than the age of the earth as determined from geological and other considerations.

In the concluding lecture, Hubble examines the distribution of the nebulæ in space, the basis of the investigation being five great surveys of some 100,000 nebulæ, two made with the 100-in. telescope, two with the 60-in. (both Mount Wilson instruments), and the fifth with the Lick 36-in. reflector; the limiting magnitudes of the surveys range between 18·1 and 20·3, and the limiting distances between 150 and 400 million light-years. On the assumption of uniform distribution, the correction dm to be applied to the observed magnitudes is found to be $2{\cdot}94\ d\lambda/\lambda$, in almost exact agreement with the energy correction of $3d\lambda/\lambda$ mentioned above. If the red-shifts had been true velocity-displacements, the procedure should have produced a correction $4d\lambda/\lambda$.

An interpolation may be made here. Recently, Sir Arthur Eddington directed attention to the fact that Dr. Hubble had omitted to take into consideration the dispersion of the absolute magnitudes of the nebulæ in his statistical investigations (*Mon. Not. Roy. Astro. Soc.*, 97, 156; 1937); however, Eddington's amended value of the correction, $3{\cdot}06\ d\lambda/\lambda$, is substantially the same as Hubble's value quoted above. But he also points out that in view of the accidental errors involved in the estimation of magnitudes, the numerical coefficient of $d\lambda/\lambda$ has a large probable error and should read: $3{\cdot}06 \pm 0{\cdot}56$, "so that the difference from the expected value 4·0 (that is, on the assumption that the red-shifts are velocity-displacements) is scarcely sufficient to constitute a discordance".

Relativistic cosmology has identified red-shifts with velocity displacements and incorporated them into the scheme of the universe. But Dr. Hubble, with the instinct of the observer, believes that the problem of the interpretation of the red-shifts is yet to be solved. In his last sentence he writes: "We seem to face, as once before in the days of Copernicus, a choice between a small, finite" (and expanding) "universe, and a universe indefinitely large plus a new principle of nature."

It remains to add that Dr. Hubble's book is a fascinating study of a fascinating subject, written in a style that many scientific authors would fain achieve and with an authority that must inevitably influence astronomical thought and outlook in the years ahead.

W. M. SMART.

Studies in Human Behaviour

(1) Psychology of Personality

By Prof. Ross Stagner. (McGraw-Hill Publications in Psychology.) Pp. xi + 465. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 21*s*.

(2) Factors determining Human Behavior

(Harvard Tercentenary Publications, 1.) Pp. viii + 168. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1937.) 10*s*. 6*d*. net.

(3) May the Twelfth Mass Observation Day Surveys 1937

By over two hundred Observers. Edited by Humphrey Jennings, Charles Madge and T. O. Beachcroft, Julian Blackburn, William Empson, Stuart Legg, Kathleen Raine. Pp. xv + 431. (London: Faber and Faber, Ltd., 1937.) 12*s*. 6*d*. net.

THE three books considered in this review, though differing considerably in their content, emphasize collectively the importance of the study of the social background of personality.

(1) Prof. Stagner's work begins in an atmosphere typical of academic psychology. He tells us that he has deliberately avoided, wherever possible, any reference to abnormal personalities, and that the book is a response to a student demand for a general text-book on 'normal' personality. The first thirteen chapters have been carefully designed in keeping with this policy, and consist largely of a résumé of some of the most important laboratory investigations in this field. This first section seems to be the weakest of the whole work, but nevertheless it should be of value to the student who wishes to find under one cover the best known experiments, theories and speculations. As a text-book, this part of the work has been well planned, and each chapter is followed by a summary and suggestions for further reading.

The second and more important part of the work, the last two hundred pages, is mainly concerned with social determinants of personality, and much of the material is drawn from the field of psychopathology. Many interesting and little-known investigations are brought together with the purpose of throwing light on various problems, such as the effect of unemployment on personality, the design of text-books for schools and their importance in the building of social attitudes and prejudices, and many other interesting and important matters.

(2) "Factors in Human Behavior"—a Harvard Tercentenary Publication—is a joint effort by eight men of science to define the forces determining human conduct. The authors are Profs. E. D. Adrian, J. B. Collip, J. Piaget, C. G. Jung, P. Janet, R. Carnap, A. L. Lowell and B. Malinowski. The value of the volume, apart from the intrinsic interest of each chapter, lies in the cross-illumination produced by the distinct viewpoints upon the central theme, each chapter discussing the problem from a different angle.

Not all the essays are of equal size or merit. First in order of magnitude and brilliance comes Prof. Malinowski's chapter. He disposes of current doctrines of mystical *Kulturgeist* and exposes the pseudo-metaphysical absolutisms masquerading as scientific anthropology. He emphasizes particularly the necessity for a strictly deterministic, functional approach to the study of cultural differences.

Prof. Collip gives us the latest results of endocrinological research. Prof. Janet expounds the interesting implications of his theory of psychological strength and weakness. Prof. Carnap reveals gaps and links between reason and unreason. Prof. Adrian gives a brief prognosis of neurological research. From Dr. Jung we get rather an operculative chapter in accordance with his well-known views, while Prof. Lowell brings a specially interesting example from British history showing the natural orderly growth of legislative integration.

All in all, this volume is an excellent instance of what scientific workers can achieve when they consent to attack the same problem from their own special points of view.

(3) "May the Twelfth", edited by Humphrey Jennings and Charles Madge, is the first of a series of 'mass observation' day surveys. The book is divided into two parts. The first part, which is the larger of the two, deals with Coronation Day and the events leading up to it. The second part deals with the general work of mass observation, of which the first part is a specific example.

The reports of the observers are given, but no generalizations are deduced from them. Throughout, one is favourably impressed with the manner of reporting events without excessive subjective bias. It would seem that even people with programmes for reforming society can be brought to distinguish between their own feelings on one hand and the objective events to be described on the other. Nevertheless, it must be clearly borne in mind that the observer will only record that which he thinks worth recording. Owing to this process of selection, any deductions based on the difference between the number of favourable and unfavourable comments recorded can have no meaning except in so far as they throw light on the reporters themselves.

The book as a whole is very readable. Criticisms of this particular approach to sociology cannot be made until it is seen how the observations are going to be interpreted. Many readers will await with interest, and perhaps some mystification, the further publications of this series.

A Jungle Tribe of Malaya

The Negritos of Malaya
By Ivor H. N. Evans. Pp. xiii + 323 + 54 plates. (Cambridge: At the University Press, 1937.) 25*s*. net.

OF the three jungle peoples of the Malay Peninsula, Jakun, Sakai and Semang, the last-named are probably the best known to the outside world. As a racial group of low stature and negroid appearance, they form a link in the chain of pygmy and pygmoid peoples extending with intermissions from West Africa to New Guinea, their nearest affinities in south-eastern Asia being the Andaman Islanders and the Aetas of the Philippines.

The distinctive physical characters and primitive culture of the Semang, as well as the question of their place in racial taxonomy, have offered a strong attraction for the interest of the anthropologist; but their reserved and elusive temperament has rendered investigation difficult. The most considerable record among those of earlier observers is that of Vaughan Stevens, a collector working in the Malay Peninsula in the nineteenth century on behalf of a syndicate of German anthropologists. Either his good fortune in his informants and his insight into Semang beliefs were exceptional, or his capacity for invention was above the ordinary. Be that as it may, the efforts of subsequent investigators, W. W. Skeat, Nelson Annandale and H. C. Robinson, Father P. Schebesta and Mr. Evans himself have been taken up to a considerable degree, either avowedly or by implication, in checking his remarkable statements—in most instances with but indifferent success.

Of investigators subsequent to Vaughan Stevens, Mr. Evans has by far the most extensive acquaintance with the Semang, or Negritos as he, more accurately and comprehensively, prefers to call them. He has been in touch with them at intervals over the whole of the twenty years of his official connexion with the Peninsula, and he has revisited them since his retirement in 1932. It is interesting to note that he is able to go further than any of his predecessors in accepting the statements of Vaughan Stevens as verified; but this does not apply to the more remarkable of the data referring to the magical meanings said by Vaughan Stevens to be attached by the Semang to the *motifs* of their decorative art. The fact that some magical meaning is attached to their decorative designs is not, of course, in dispute.

It may appear that too much stress is laid on the question of Vaughan Stevens's credibility. That question, however, is fundamental; and all the more in Mr. Evans's work, because in presenting what is evidently intended to be a definite account of the Negritos—and it is scarcely probable at this late date that much of value will be added—he has made Skeat and Blagdon's monumental "Pagan Races of the Malay Peninsula", in which in relation to the Semang the critique of Vaughan Stevens is an important element, his starting-point. To this he has added a digest of the work of subsequent investigators, extending and criticizing it in the light of the observations which he himself has made. This applies more particularly to the material culture and the involved and complex religious beliefs of the Negritos, to knowledge of which Mr. Evans has made notable contributions; but for linguistics and physical anthropology he has to rely mainly on Dr. O. C. Blagdon's masterly study of the languages of the Peninsula, and for physical characters on Lebzelter's analysis of the data collected by Schebesta, which is the most considerable body of material extant.

The Negritos are now said to number a little less than two thousand. They undoubtedly have been subjected to much racial admixture. They are very variable in physical character, unlike the Andamanese, who are strikingly uniform. Being a lowland and river valley people, they have been much in contact with the Malays, in relation to whom their present condition is described as "servile".

Mr. Evans describes the very primitive material culture of the Negritos in detail. It is interesting to note that the bow, the characteristic weapon of this people, has been superseded almost completely by the Sakai blow-pipe, and indeed among some of the Negrito tribes it has been entirely forgotten.

In elucidating the obscure religious beliefs, with the extensive system of divine beings, Mr. Evans arrives at the conclusion that these are ancestors; but he makes the interesting and instructive suggestion that the explanation given of the origin of these divine beings—that they were the individuals who escaped to heaven and became deities because their hair had not been frizzed in the battle between the monkeys—may be derived from the Ramayana. Attention may be directed also to his remarkable and fortunate record of the shaman in action, an interesting and important matter on which little or nothing in detail was known previously. Mr. Evans was the first European to be present at a shamanistic performance and the first to describe the shaman's hut.

On the broader question of the ethnological position of the Negritos, Mr. Evans has little to add to what has been said by others. From his archæological investigations, however, he makes one important contribution. In relation to the question whether the pygmy people represent the earliest entrants into the Peninsula, he points out that the skeletal remains of the inhabitants of the caves belonging to the palæolithic-neolithic transition period investigated by him were not those of a Negrito type, and that this type does not appear until relatively late in the archæological succession.

Culture-Contact in India

A Tribe in Transition:
a Study in Culture Pattern. By Dr. D. N. Majumdar. Pp. xi + 216 + 5 plates. (Calcutta, London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 10*s.* 6*d.* net.

DR. MAJUMDAR'S book aims at doing something more than merely giving us an account of the Hos of the Kolhan. This indeed he does not neglect, but his particular purpose is to show them as they have reacted and continue to react to the effects of contacts with their Hindu neighbours. He states as his methodological ideal a synthesis of Malinowski's approach in "The Argonauts" with that of Ruth Benedict in "Patterns of Culture", but his adherence to their methods is by no means overstressed. He gives a comprehensive account of the social culture of the Ho, who clearly retain a very great deal of their typical culture in spite of their many contacts with Hinduism, which have influenced in particular their marriage ceremonies and festivals.

Dr. Majumdar seems inclined to accept the view that the Ho originally migrated southwards from the Himalayas. He mentions that the language used in spells is non-Austric, but does not specify what language actually is used. Vestiges of totemism seem to exist, though repudiated as such by the author, and there has clearly been a megalithic cult, now so generally decadent that menhirs do not seem to be erected at all, though horizontal slabs of stone are still provided for the dead.

The institution of bachelors' dormitories is considered as definitely fostering homosexuality, and this is remarkable, since generally speaking the bachelors' dormitory system, both in Assam and in Chota Nagpur, does not seem to have that effect at all. One's confidence in the author is rather severely shaken by finding that he imputes the custom of marriage by capture to the Naga Hills, and he is surely wrong in supposing that the claim on the part of a married woman's patrilineal family to the half of her bones is something new, unless it is in their not demanding the whole. The custom of returning the woman's bones to her own clan is the more ancient, and in a Munda marriage there is always a formal stipulation by the bride's clan that the bones shall be returned, although it is not really intended by either party that the promise to do so shall be implemented; in Assam a 'bone-price' is paid as a quittance for the obligation to return them.

Zoological references are obscure and the Latin names unfamiliar: the corsac fox is surely not the one usually found in India, which is more familiar as *Vulpes bengalensis* than as *Cynalopex insectivorus*; the sambar (referred to as "saumer") is generally classified as *Rusa*, not as *Cervus* by genus, and one is left guessing what is meant by "grower" and by "red deer". A map is very badly needed, and likewise a glossary to explain to the English reader such words as *birdiring*, *ficca*, *sonta* or *hatu*. Material culture is poorly treated; tattooing is mentioned, but pigments and processes are not described; and with no illustrations to help one the descriptions of objects (for example, of a plough on p. 6) are very difficult indeed to follow. On the whole, however, the book is an important contribution to Indian ethnography, particularly in its estimate of the impact of Hinduism on the culture of the Hos, and marks a rather new departure in Indian ethnographical literature.

J. H. H.

Hunting by Scent

The Mystery of Scent

By Hugh B. C. Pollard. Pp. xix + 139. (London: Eyre and Spottiswoode, Ltd., 1937.) 10*s.* 6*d.* net.

THE vagrant nature of odours would seem to be symbolized by a word-errant in search of a meaning. Scent, for example, according to a dictionary, signifies "odoriferous particles, odour, smell, fragrance; a class or one of a class of sweet-smelling, aromatic substances used for perfuming; sense of smell; odour left by the animal on the ground or surface passed over". It is the latter meaning that is mainly implied in the title of Major Pollard's book. He discusses principally the relatively complex conditions which control the diffusion of scent, and has worked out a simple instrument which will tell the hunting man the chance of scent on any day.

It is claimed to be a practical book for fox-hunting people rather than a scientific discourse. However, a racy style does not altogether mask the large quantum of science lurking in its pages ready to engage the attention of the reader and to exact his interest. The expert in ballistics proves himself to be also an adept in firing data and problems, physical, chemical and biological.

The correlation between scenting and meteorological conditions was discussed from different points of view in "Hunting by Scent" by Mr. Budgett (NATURE, **133**, 548–549; 1934), and in a pamphlet on "Scent and the Weather" by Flight-Lieut. Veryard (NATURE, **136**, 60; 1935). Major Pollard explains the development of a relatively large volume of scent from the small amount secreted by the pad glands of the fox, by suggesting that fox scent is an extremely volatile compound with marked capacity for spreading on water as a monolayer and being dissipated on water vapour. There are good reasons for doubting that the foxy (fur or bedding) scent we know is what hounds really hunt. The true 'scent' or pad secretion at each footstep is small, but on a still day the emanation from a series of pad marks was observed to form a band 15–20 yards broad, and, on a windy day, hounds are able to pick up a line even on a broader front.

The best scenting conditions prevail when the evaporation near the surface of the ground is at its maximum. The range and variation of the meteorological factors on a normal hunting day are much wider than is usually realized. No one factor alone controls scenting. The 'Pollard scentometer' (Prov. Pat. No. 26346), which is now marketed by the publishers, raises the prediction of hunting conditions in the course of the day from intelligent guesswork to a reasonable degree of fore-knowledge. The instrument comprises a thermometer, hygrometer, and an arrangement of five circular concentric dials which are set to the temperature, degree of humidity, relative amount of cloud, quarter of the wind, and wind velocity. The lower part of each dial is provided with numerical values for scent, which are read between two parallel wires and added up from the bottom to the centre. The sum represents the percentage of scent to be expected within the next few hours.

Major Pollard has also much of interest to relate about scent in other animals, about scent and local conditions, and a number of other problems, new and old, and all discussed in a stimulating manner. His book should certainly stimulate further research on such problems as that of adsorption and on the electrical phenomena in odorous vapours, and also the comparative study of the role of pigments in the olfactory mucous membrane and cognate subjects. J. H. K.

Plant Physiology for Students

General Plant Physiology

By E. C. Barton-Wright. Pp. 539. (Williams and Norgate, Ltd.) 15*s.* net.

PLANT physiology—especially the teaching of it—has not been in a satisfactory state for decades, and though one is constantly looking for signs of improvement, prospects are not reassuring. It seems worthy of reflexion that the first-class plant physiologist of the future must be the almost exclusive enthusiast of the present; for few ordinarily promising students are being attracted to the subject.

Until recently, one of the apparent reasons for this was the dearth, in fact, absence, of text-book reading for elementary students. There were no British text-books of university first degree standard, and the few American books, though worthy, seemed quite unknown. Students were forced to depend on their lecture notes (hence on the educative powers of their teachers) and on the out-of-date English translations from well-known German texts. Now, this reason has gone, for during the past three years three text-books of the required standard by British botanists have appeared.

Two have already been favourably reviewed in these columns, and now the third, by Dr. Barton-Wright, can be received with equal favour; but only as a text-book satisfying the courses prescribed for first degrees in the universities. It is, as the author claims, "meant as a general survey of plant physiology". After having read the text, one agrees with this claim, yet with a feeling of misgiving as to the necessity for such a book. The other two text-books were surveys of the subject made by well-known authorities; in a third book appearing so soon after, one is justified in looking for a distinctive feature or features. It was with disappointment that we finished reading this survey, for no such distinctiveness could be found. From the student's point of view, however, it has the advantage of a comparatively modest price.

The book reviews the science of plant physiology very thoroughly, but, like the others, seems to be a morass of fact and theory, very loosely bound together, with little sifting or evaluation. Merely to state all relevant facts and to quote the most discussed theories, is, of course, a safe policy for the author. But what about the student? He is not reading a monograph, but rather feeling his way, and needs a hint now and then to avoid blind alleys. It is a pity that the academic plant physiologist does not seem to realize this. It is true that Barton-Wright has made a choice of matter here and there; but the choice is the same as has always been made hitherto. Theories of transpiration are considered, for example, in the usual way—mentioning, dismissing, mentioning, dismissing and culminating in a detailed consideration of Dixon's cohesion theory. It will be interesting to see how this topic will be treated in the next text-book in view of the work of Dr. P. R. White of the Rockefeller Institute for Medical Research, which has recently been recognized by the thousand-dollar prize of the American Association for the Advancement of Science. It will indeed be refreshing if White's work only causes a slight modification of the treatment of this subject.

These remarks are not directed against the book under notice specifically, except in so far as the author has allowed himself to be fettered by tradition. Indeed, at times, he does take a point of view, and talks to his readers instead of merely presenting a critical résumé of work done and theories propounded. Nevertheless, many physiologists would not agree that the "ultimate goal [of physiology] is to explain them [living processes] in terms of physics and chemistry". The statement is dangerously narrow to make to a young student. Also, whether the late Sir J. C. Bose was the head of a school of investigators which holds vitalistic views is a moot point. Bose's main theses were that response in the plant organism is identical with that of animal muscle and nerve, and that much in the living world finds its counterpart in the inorganic; this is not the same thing.

Barton-Wright is very thorough in his survey of the literature; in fact, all his publications have shown this characteristic, so that students may be sure that in following his text they are missing little of importance so far as reading for a degree is concerned. The book is good value for the money.

South African Earthworms

A Monograph of the Acanthodriline Earthworms of South Africa

By Dr. Grace Evelyn Pickford. Pp. 612. (Cambridge: W. Heffer and Sons, Ltd., 1937.) 25*s*. net.

It has been frequently pointed out that the advancement of systematic zoology is best served, in the present state of the science, not so much by the description of new species as by the revision and putting in order of the species that are supposed to be already known. Of the kind of work that is most needed, an excellent example is provided by this monograph by Dr. Grace Pickford. The laborious investigation of the very large collections made in South Africa by the author and by others seems to have been done with great thoroughness and care. The results are set forth in very clear fashion and—so far as a non-specialist may see—with sound judgment.

A volume of more than six hundred pages may seem a liberal allowance of space in which to deal with a single sub-family from a single geographical region, but, as is pointed out in the preface, there are very solid reasons for giving special attention to this particular group in this particular area. The Acanthodrilinæ represent the most ancient element in the earthworm fauna of South Africa, and their relations to the faunas of other regions in the southern hemisphere present important problems which have not yet, perhaps, been completely solved. Further, as the late Dr. Michaelsen pointed out long ago, they have, in South Africa, become differentiated into a large number of local forms, often with very restricted ranges.

In the present volume, 85 species and 44 sub-species and races are recognized. The delimitation of the areas inhabited by these and their relation to the phylogeny of the group and to the geographical and climatic changes in the recent geological history of South Africa are discussed in a series of chapters of great interest.

A mild protest may be recorded against some of the terminology used in this volume. It is doubtful if much is gained in brevity or in clarity by the use of such words as "speciation", "sub-speciation" and "raciation". The printing is not above criticism, and surely the printers' reader ought to have known how to spell "desiccation".

W. T. C.

A New Continent

Soviet Geography: the New Industrial and Economic Distributions of the U.S.S.R. By N. Mikhaylov. Translated from the Russian by Natalie Rothstein. Second edition revised by the author. Pp. xviii + 229. (London: Methuen and Co., Ltd., 1937.) 10*s.* 6*d.* net.

IN a foreword to this book, Sir Halford Mackinder describes it as "a political pamphlet of the indirect order". There is not much indirectness in its politics for scarcely a page omits to contrast the blessings of the Soviet régime with the backwardness of old Russia. The tables of figures, plentifully supplied, include, as if they were facts, the estimates of the second 'plan', and the reader is asked to believe that "the industry of the U.S.S.R. . . . works according to plan, and knows nothing of crises".

But when one has discounted the propaganda, there remains in this work enough of fact to arrest attention. M. Mikhaylov claims that the Soviet Government has discovered a new continent, and this is not far from the truth. Further, it is exploiting that new land as rapidly as it can profitably do so. New industrial centres have been set up, as for example in the southern Urals, with its new towns of Magnitogorsk and Khalilovo, or in the Kuznetzk basin of west Siberia. Old industries, such as the iron industry in Leningrad and the textile industry of Moscow, which formerly depended largely upon imported raw materials, are now drawing their supplies from within the Union. Irrigation works have been extended, and crops suitable for dry areas have been introduced where irrigation is not possible. Agriculture is being revolutionized through collectivization. "The fierce resistance of capitalist elements in the villages was overcome" and the "agricultural machines", the "organization of the sovkhozes" (large-scale State agricultural enterprises), and the financial support of the Government are completing the process. It is unnecessary to continue the catalogue of development. M. Mikhaylov sets it out with an insistence and a dogmatism that make the reader wonder if it is all as nice and as satisfactory as it is pictured. Between 1913 and 1934 the "individual peasants" were reduced from 65·1 per cent of the population to 22·5 per cent and the bourgeoisie and the Kulaks have been nearly eliminated. On the other hand, the numbers of industrial workers have been doubled. This process is inevitable if one accepts the author's dictum that "the development of backward agriculture and the general industrial development of the country could not be achieved on the basis of petty individual peasant farming".

Here is the clue to the new 'Soviet geography'. To a land of boundless resources is being applied a plan of exploitation which is none the less ruthless because it is scientific. Russia as it was known in 1913 is moving eastward and northward into desert, and forest and tundra; railways, aeroplanes and ice-breakers are helping the process. How much—and relatively how little—has been done is revealed by the map showing the distribution of population. But, as M. Mikhaylov says, "the new geography of the U.S.S.R. . . . is not a spontaneous development but the accomplishment of a plan". The million people now living in the north-east quarter may some day approach more closely in number to the eleven millions in the Moscow province or the thirty-one millions in the Ukraine; but for all his assurance one can legitimately doubt if even M. Mikhaylov really believes that their lot will be one of "abundance and happiness".

J. N. L. B.

Industrial Catalysis

Catalytic Processes in Applied Chemistry

By Prof. T. P. Hilditch and Dr. C. C. Hall. (Monographs on Applied Chemistry, Vol. 2.) Second edition. Pp. xxii + 478. (London: Chapman and Hall, Ltd., 1937.) 25*s*. net.

THE subject of industrial catalysis continues to develop rapidly; such processes are the rule rather than the exception. There is a vast literature dealing with them and a rapid increase in the number of special books relating to particular aspects of catalysis. It is all the more valuable, therefore, to have a more general treatise brought up to date, especially as the new edition is characterized by the same clarity of expression as the former.

Notable examples of new catalytic processes are those involving polymerization, for example, the production of petrol and even of lubricating oils from the small hydrocarbon molecules in 'cracked' gases; or those in which the higher fatty alcohols are made from the fats by high-pressure hydrogenation in presence of copper-chromium catalysts. This group of substances, previously largely unknown, is the basis of a new class of detergents.

The subject is so intricate that it has been found necessary to introduce classified lists of processes, products and catalysts, with page references at the beginning of the book.

The chemist is acquiring remarkable powers; with the aid of a variety of catalysts and variations in temperature and pressure, he is able, for example, to produce from the one raw material, water gas, either methane, pure methyl alcohol, higher alcohols, acetic acid or petrol hydrocarbons in a range extending from butane to waxes, and to vary the proportion of these; other catalysts enable him to remove the sulphur compounds from water or town's gas or the carbon monoxide from hydrogen. A single catalyst—copper—may be used for half a dozen different reactions under different conditions.

It is about a hundred years (1835) since catalytic changes were first so called by Berzelius, and about sixty years (1875) since Squire and Messel began to make sulphuric acid at Silvertown by the catalytic action of finely divided platinum. The Norman process of fat hardening was made a practical one by the firm of Crosfield's, at Warrington, about 1910—much the same time as the Haber-Bosch process for synthetic ammonia.

Since those days, there has been a spate of catalytic processes. Prof. Hilditch has worked in the industry, published important researches and taught the subject; so he has triple qualifications for providing an up-to-date work on it.

Primes and Factors

Factor Tables giving the Complete Decomposition into Prime Factors of all Numbers up to 256,000

By Dr. George Kaván. Pp. xii + 514. (London: Macmillan and Co., Ltd., 1937.) 42*s*. net.

DR. GEORGE KAVÁN was born at Prague in 1877. His parents were Francis Kaván, a musical conductor and a composer of merit, and his wife Miroslava, an ardent supporter of the civil rights of women. After studying mathematics, physics and astronomy, Kaván became in 1900 chief assistant at the Astronomical Institute of the Czech University at Prague, where he remained until his appointment in 1919 as director of the Observatory at Stará Ďala. The Observatory being at that time not fully equipped with instruments, it was found possible to use part of the publication funds to cover the cost of printing the present handsome volume of tables. The calculation was started in 1917, and after the author's death in 1933 his wife, Madame Kavánová, undertook the reading and correction of the final proofs.

The work is preceded by a preface in English by Dr. Šternbeck of Stará Ďala, an introduction by Dr. A. Beer, now of the University of London Observatory, a preface in Latin by Prof. K. Petr, and a foreword in Czech by Kaván himself explaining his reasons for making the present table, and another of Euler's function $\varphi(n)$ which gives the number of integers less than n and prime to it. The greater part of this latter is already in type and should be published shortly. It appears that Kaván was largely influenced by Cayley's expression, in the British Association Reports, of the need for these tables. Cayley, for example, makes the point that in the theory of numbers the decomposition of $p-1$ where p is prime is frequently required.

Given an integral number less than 256,000, this book gives *immediate* information as to its prime or composite character and, if composite, its complete resolution into prime factors. The emphasis is here essentially on the adjective "immediate", for tables (by D. N. Lehmer) are available giving the smallest prime factor of every integer, less than 10,017,000, which is not divisible by 2, 3, 5, and so allowing the factorization of any integer up to this limit. But the labour of producing the factors may still be very great, so much so indeed that the British Association Tables Committee issued in 1935 a table of complete decompositions of all integers less than 100,000, which was then the longest list of decompositions of consecutive integers. Kaván's work is more than two and a half times as extensive.

The tables are arranged to read horizontally from left to right across the page. The leading figures are found in the left-hand column, the terminal digit 0, 1, . . . , 9 being across the top of the page. This was the arrangement suggested by Cayley, and seems easier of reference than the Chinese method of vertical columns read downwards which has also been used in this type of table. In such tables the tabular value is only another aspect of the argument; we have in fact a table of x with x as argument. The printing is clear, and a bold clarendon type distinguishes the prime numbers; a captious critic might suggest that figures with heads and tails would have been even more appropriate for the tabular values.

The method of calculation is described in Dr. Beer's preface, and, what is more important from the user's point of view, the precautions which have been taken to ensure the greatest possible accuracy. All the decompositions were checked by re-multiplication. The decompositions were compared with those in the tables of Inghirami (1832), of Goldberg (1862), and of Chernac (1811). After printing, a last check was made by comparing the decompositions of all numbers x with those of $2x$, $3x$, $5x$. Those numbers which evaded this check were again compared with Chernac's values.

The table was used by Kaván as a basis to calculate the function $\varphi(n)$ mentioned above, in the course of which errors in the table would have been revealed. A list of 24 errors is given at the end of the book, together with a version of certain entries where the type impression is poor. It is therefore reasonable to suppose that the work will contain few, if any, undetected errors.

All those responsible may be congratulated on a fine piece of work, nobly conceived, ably executed and worthily printed.

L. M. Milne-Thomson.

Developments in Theories of Integration

Modern Theories of Integration
By H. Kestelman. Pp. viii + 252. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 17*s.* 6*d.* net.

THE author of this book complains that while Lebesgue integration is everywhere firmly established as an essential part of the theory of functions, its treatment in English text-books "remains unsatisfactory and uninfluenced by the simplified treatment of Carathéodory". The account of the Lebesgue integral he gives follows closely the lines of Carathéodory's "Vorlesungen über reelle Funktionen". The Lebesgue theory of measure forms the basis of a theory of integration from which the principal defects of the Riemann theory are absent. The Lebesgue integral is a generalization of the Riemann integral, and the Lebesgue theory of measure allows an enormous extension of the solution of the problem of areas only partially solved by the Riemann integral (or by the theory of Jordan content).

The author devotes a chapter to Riemann integration in order both to establish conditions in which it exists and to discuss its relation to problems such as the integration of derivatives and of limit functions in general. It is only by appreciating the circumstances in which the Cauchy-Riemann integral is insufficient that Lebesgue's achievement can be appreciated.

The extensions of the Lebesgue integral are traced from Hölder's definition to that of Denjoy; and the general Denjoy integral is developed without the use of transfinite numbers. This treatment is derived by the author from a paper by P. Romanovski. A chapter on Fourier series illustrates the application of Lebesgue theory to a branch of analysis for which it has been of the utmost importance.

The book begins with a chapter on the definitions and elementary theorems of the theory of aggregates, particularly of sets of points, and develops them so far as is necessary for an understanding of the theory of the Lebesgue integral. Here, proofs of several theorems depending on the existence of certain aggregates for which no rule of 'construction' was forthcoming, are legitimatized by the introduction of Fraenkel's axiom of selection. This axiom is specially invoked to prove that every infinite set contains a sequence of distinct points and it is often used implicitly in existence theorems.

A. v. Z.

Short Notices

Anthropology and Archæology

Chinese Fairy Tales and Folk Tales

Collected and translated by Wolfram Eberhard. Pp. xiv+304. (London: Kegan Paul and Co., Ltd., 1937.) 10*s*. 6*d*. net.

THIS collection of Chinese fairy and folk tales—'ghost', perhaps, would have been more accurate than fairy—differs from most with which the Western world is familiar in the fact that the collector has had them direct from the mouth of the people, and has eschewed the printed source. It may be doubted, however, how far the distinction is to be regarded as an essential difference, even though certain classes of story are absent. On Herr Eberhard's own showing, the Chinese folk-tale is the product of an attitude of mind towards the spirit-world, which is so far an effective element in every-day life, and not solely an attribute of children and the unsophisticated, as in Europe, that the product of the myth-making faculty can still be reported in a daily paper as a statement of fact. An example is quoted in the preface—a story of how a policeman became a city-god—which might equally well have appeared in the text.

Herr Eberhard states that he has made a very large collection of Chinese folk-tales, which will be published shortly. The present collection contains a selection only, and from the point of view of scientific study suffers from the fact that no indication is given of distribution or provenance. It must be regarded, therefore, as entertainment. The student of *motif*, however, will find much of interest. Early relations with India and the West must be held responsible for the appearance of Cinderella and the slipper, the three sons, and various forms of the task to be performed before marriage, inheritance, or other reward, especially in that in which it is familiar in the legend of Psyche. A number of other *motifs* which appear in European folk-lore will be found here but little changed in essentials, notwithstanding the Chinese setting. The "happy ever after" ending, however, is not invariable.

As literature, the collection is delightful and the translation lively and easy in style.

The Archæology of Sussex

By E. Cecil Curwen. (The County Archæologies.) Pp. xviii+338+32 plates. (London: Methuen and Co., Ltd., 1937.) 12*s*. 6*d*. net.

THE county of Sussex as a whole affords a more than fair sample of the characteristic cultures of an English lowland area; but its most famous contribution to the study of early man is unquestionably the Piltdown skull. Dr. Curwen records the circumstances of its discovery and the discussions as to its character and rank in the human line of descent which then took place; but presumably he regards later argument as a specialized matter scarcely falling within his province. In the earlier problems of prehistory, the county is also of importance for the evidence of the raised beaches of western Sussex.

In the mesolithic period, Sussex is notable for the discovery of microlithic implements so early as 1877 at Horsham. It includes within its boundaries a number of mesolithic stations on the greensand, which are especially significant as demonstrating mesolithic man's preference in the matter of sites for his occupation. This was also the first area in England to afford evidence, at Hassocks, of a mesolithic pit-dwelling.

Of other matters with which Dr. Curwen deals, attention may be directed more especially to his reconstruction of life on the downland in the neolithic period, for which evidence is afforded by flint mines, long barrows, camps and the like, and his admirable account of the late bronze age material, more especially the Plumpton Plain A site, where there appears the earliest known example in Britain of the introduction of the Celtic system of agriculture.

The volume concludes with a survey of Roman Sussex; the Anglo-Sussex period and the gazetteer, which have appeared in previous volumes, are omitted.

Astronomy

Sunspots and their Effects

By Harlan True Stetson. Pp. xv+201. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 8*s*. 6*d*.

THE whole life of the earth depends on the sun, and it follows that variations of solar activity should be reflected in terrestrial phenomena. In this book, Dr. Stetson gives a popular exposition of this thesis, and especially of the idea that changes in the sun associated with sunspots may have physiological or emotional effects on human beings which cause them to behave differently at times of many or few spots. This influence, if indeed it exists at all, is most probably related to the physiological action of great variations of ultra-violet radiation during the sunspot cycle, though the possibility of an electrical action is also considered. Changes of energy and confidence are reflected in various aspects of business, as shown by parallelism between economic indexes and sunspot numbers over the last few decades. The statistical basis is insufficient for proof, but the presentation is suggestive.

The author also has a good chapter on sunspots and radio, but the discussion of relations with weather and crops is brief and superficial. The second half of the book presents in a very readable way modern ideas on sunspots themselves—their causes, the migration of sunspot zones and the possible reasons for their quasi-periodic recurrence. The author is an astronomer, and for the general scientific reader this is the best part of the book.

Astronomy

By Prof. W. M. Smart. (The Pageant of Progress Series.) Pp. 158+24 plates. (London: Oxford University Press, 1937.) 3*s.* 6*d.* net.

THIS book provides an excellent summary of astronomical information which should be known by the average person interested in this science. It is written in simple and non-technical language, and will prove very readable to a large section of the public. Commencing with the earth, it extends its scope to the moon, planets, comets, meteors, the sun, and then to the extra-solar system bodies—stars, nebulæ, etc. In covering such a wide field it is inevitable that only a brief survey can be made of the various branches, but it is amazing how much up-to-date information Prof. Smart has condensed in such a small space. The book is illustrated with 24 plates and 38 diagrams, which greatly enhance its value and interest. Its modest price brings it within the reach of a large circle of readers, and we anticipate that it will be included in the category of 'best sellers.'

There are a few points to which reference might be made, though they are trivial. Dr. Jeffreys does not now believe that there is a layer of ice 16,000 miles thick on Jupiter (p. 52). It is implied that meteors move with parabolic velocity. The results of the Harvard College Arizona Expedition six years ago showed that most sporadic meteors were moving with high hyperbolic velocities, often as much as 120 miles a second (p. 75). On p. 130, line 10 from the top, the letter "C" should be substituted for "B."

M. D.

Biology

British Stem- and Leaf-Fungi (Cœlomycetes):

a Contribution to our Knowledge of the Fungi Imperfecti belonging to the Sphæropsidales and the Melanconiales. By W. B. Grove. Vol 2: Sphæropsidales, comprising Sphærioideæ, with Coloured Spores; Nectrioideæ, Excipulaceæ, and Leptostromataceæ; and Melanconiales. Pp. xi+406. (Cambridge: At the University Press, 1937.) 21*s.* net.

"UNFORTUNATELY the literature of mycology consists largely of fragments, memorials of splendid designs never prosecuted, of good intentions never fulfilled. We cannot but call to mind one after another the splendid works we might have consulted had they attained completion." Thus wrote M. C. Cooke, the noted English mycologist, in 1875, and the position remains much the same to-day. With the publication of this second and final volume, however, the late Mr. Grove joined the select company of those who have completed a flora of their country's Cœlomycetes, and has become, in fact, the first to do so in the English language; it is a crowning achievement to his long career.

This final volume follows the lines laid down in the first, and finishes with three indexes and an epilogue. In the latter the author explains his aim, which has been to give a panoramic view of Saccardo's classification, in so far as it is illustrated by the British species. He has successfully accomplished this aim, and in so doing has been led into a rather severely conservative treatment of large numbers of proposed new genera; the latter may, however, be traced in the synonymy of the various species. An index of Ascomycetes that have been proved (or thought) to represent the perfect form of various Cœlomycetes is an interesting and suggestive feature, and may perhaps attract fresh workers into a fascinating field that has been so unaccountably neglected by our university students.

British mycology is indeed indebted both to the indefatigable zeal of the author in completing the work and to the Cambridge University Press, which has provided a dignified and worthy setting.

E. W. M.

Practical Zoological Illustrations

Part 1: Vertebrates. By S. Lockyer and D. R. Crofts. 28 cards, 14½ in. × 9½ in., in Portfolio. (London: Macmillan and Co., Ltd., 1937.) 10*s.* 6*d.* net.

THE types chosen for this series are those used in the junior class, namely, the dogfish (10 cards), frog (9 cards), and rabbit (7 cards). One sketch of the sheep's heart has been added. The large, clear drawings have been admirably executed by the junior author, and are based on actual dissections. They represent faithfully the relative disposition of the organs, and will therefore be helpful for beginners who find difficulty in interpreting verbal directions. Whether it is wise to train a student of pure science by this means is very doubtful. Let him rather explore the unknown, even at the risk of early failure.

The interpretation of the dissections falls somewhat short of their execution and delineation. The following structures, all of which would be visible when the dissections were made, have been omitted: the pancreatic duct (I), the buccal branch of the facial nerve (IX), the ilio-hypogastric nerve (XVIII), the corpora cavernosa (XXII), the glosso-pharyngeal nerve (XXIV), and the moderator band (XXVII). Several mistakes should be rectified. The student who looks for the internal opening of the oviduct in the frog will not find it directed mesially as on Card XIII. The seminal vesicle has been wrongly labelled on Card XIV, the coeliaco-mesenteric artery does not arise from the dorsal aorta as shown on Card XVI (see Ecker, 1896, p. 301), the rabbit's *hepatic* portal vein has been labelled *renal* portal (XXV), and in the sheep's heart the hemiazygos vein has been converted into a left superior vena cava, a vein which is lacking in the sheep, as in the majority of mammals.

Fundamentals of Bacteriology

By Dr. Martin Frobisher, Jr. Pp. ii+474+4 plates. (Philadelphia and London: W. B. Saunders Co., 1937.) 14*s.* net.

BACTERIOLOGY is no longer an exclusively medical subject. Most of the bacteria are harmless, many of them are useful, and their study is of importance to students of botany, physiology, industrial processes and agriculture. Further, from a cultural and philosophical point of view, the study of bacteria as microscopic plants, broadens the student's interest in living organisms and deepens his appreciation of the intricacies of Nature.

It was with these considerations in mind that this volume on bacteriology has been written ; the treatment of the subject is unspecialized, and its various aspects—medical, industrial, agricultural and others —are discussed on broad and general lines, and anyone adequately grounded in elementary biology may study it with profit, and, we would add, with enjoyment. The book contains a wealth of reliable and up-to-date information, comprising classification and biology, cultivation and methods of investigation, descriptions of species and their connexion with processes, with final chapters on viruses, pathogenic Protozoa and the history of bacteriology.

The book is most readable and fully illustrated with figures and plates (some coloured), including reproductions of portraits of many pioneers, and of pictures illustrating processes and the like, which add to its interest. R. T. H.

A Guide to Veterinary Parasitology:

for Veterinary Students and Practitioners. By Dr. T. Southwell and A. Kirshner. Pp. x + 144. (London : H. K. Lewis and Co., Ltd., 1937.) 7*s.* 6*d.* net.

THE veterinary profession has made conspicuous progress during the last fifty years in education, usefulness, public estimation and consequent reward. No branch of the medical profession has been more quick and eager to make use of the discoveries of the age. At Onderstepoort and at Aberdeen, for example, veterinary science has great scientific institutions of its own, and this little book before us, prepared within the Liverpool School of Tropical Medicine, shows how the young veterinarians extend their experience and their education. The book needs no lengthy notice. It is a student's book, short and elementary, but lucid and sound. The pathogenic Protozoa are treated very briefly, but the introduction will serve; and the young 'vet.' who goes to South or East Africa will soon learn a great deal more. The parasitic worms are amply, though very concisely, described ; and the many illustrations, which seem to be all quite new, will hold their own against those in any text-book of zoology. D. W. T.

The Fauna of British India, including Ceylon and Burma

Edited by Lieut.-Col. R. B. S. Sewell, assisted by G. Talbot. (Published under the patronage of the Secretary of State.) Moths, Vol. 5 : Sphingidæ. By T. R. D. Bell and Lieut.-Col. F. B. Scott. Pp. xviii + 537 + 15 plates. (London : Taylor and Francis, 1937.)

A NOTABLE feature in the present volume of this well-known series is the amount of information it has been possible to give on life-histories and metamorphosis. A large number of Indian Sphingidæ, or hawk-moths, have been reared by the authors, who made careful descriptions of their early stages and habits. Something is now known of the metamorphoses of 66 per cent of the Indian species and of 85 per cent of the genera. Almost all the fifteen plates are given to illustrating larvæ, or in some cases, pupæ, while the imagines are for the most part represented in the text-figures. We look forward to the time when other volumes on the moths of India can provide an equal wealth of biological data.

The taxonomy followed is that of Rothschild and Jordan's "Revision of the Sphingidæ". This work, together with later writings of these authorities, has also been extensively drawn upon in other ways in the preparation of the volume. Valuable help has also been given by Mr. W. H. T. Tams, of the British Museum (Natural History). We need only add that the authors, and others concerned in its production, are to be congratulated on the publication of a volume which should long remain the leading source of information on its subject.

A Guide to Collecting Butterflies of India

By Lieut.-Col. H. D. Peile. Pp. xiv + 312 + 25 plates. (London : John Bale, Sons and Curnow, Ltd., 1937.) 25*s.* net.

THIS manual provides an account of those of the Indian butterflies most likely to be met with in the general course of collecting. It is intended for beginners, is of handy size and admits of easy reference. As many forms as possible are accurately figured from drawings made by the author, and notes on the habits, food-plants, etc., of numerous species are given. At the end of the book is a number of local lists of species found in various districts of India, and the nomenclature followed is mostly that used by Evans in his 1932 volume. The book should prove a useful aid for the novice, and perhaps do something towards inducing him to become something more than a collector of specimens.

More Songs of Wild Birds

By E. M. Nicholson and Ludwig Koch. (Bird-Lovers' Manuals.) Pp. viii + 104 + 29 plates. (London : H. F. and G. Witherby, Ltd., 1937.) With 3 double-sided gramophone records, 15*s.* net.

THIS little book supplements an earlier volume on "Songs of Wild Birds" noticed here a year ago (NATURE, 139, 132; 1937). Like its predecessor, it is a 'sound book'—illustrated both pictorially and by accompanying gramophone records, which are not obtainable separately. Mr. Nicholson having already given his general ideas on the subject of bird-song, the text on this occasion is largely occupied with incidental matters, such as the methods used and the difficulties experienced in securing records of birds singing in a wild state. There is also a chapter dealing with woodland, park and heath birds, including species which are not songsters in the ordinary sense. Some of the latter are recorded, and the reproduction of the curlew's cry is notably successful. The number of records has been increased from two to three, and the six sides comprise twenty-two items : the quality testifies to the skill, enterprise and patience of those responsible.

Chemistry

Laboratory Methods of Organic Chemistry

By L. Gattermann. Completely revised by Heinrich Wieland. Translated from the twenty-fourth German edition by Dr. W. McCartney. Pp. xvi + 435. (London: Macmillan and Co., Ltd., 1937.) 18*s*. net.

THAT German text-books ought to be translated into English is by no means certain; but of the value of translating a manual of practical organic chemistry there can be no doubt; for such a book is required in the earlier years of a student's life, usually before his knowledge of German is very profound.

Since its first publication in 1894, Gattermann's "Laboratory Methods of Organic Chemistry" has been the most widely used practical chemistry of the German universities, and it has been available since 1896 to English-speaking chemists in the American translation of Schober and Babasinian. Twelve years ago the book was rewritten by Wieland, and a translation by Dr. McCartney was published; since then it has again been revised, and it is this revised edition that Dr. McCartney has now translated.

The familiar lines have not been altered. After sections on general methods of manipulation and organic analysis comes the main preparative section, appropriately prefaced by two pages on the prevention of accidents. In each chapter of this section one or two preparations are first given, followed by several pages of explanation, which in turn lead on to further preparations.

This combination of theory and experiment makes the book a really excellent one for the teaching of organic chemistry. A possible criticism is that the price is rather more than most students expect to pay for a practical book; but then "Gattermann" is more than a practical book. B. K. B.

Toxicity of Industrial Organic Solvents

Summaries of Published Work compiled by Dr. Ethel Browning under the direction of the Committee on the Toxicity of Industrial Solvents. (Medical Research Council: Industrial Health Research Board. Report No. 80.) Pp. iii + 388. (London: H.M. Stationery Office, 1937.) 7*s*. 6*d*. net.

THE wide use of organic chemicals as industrial solvents has introduced certain complications, including a possible danger to health. Whilst the solvents are perfectly safe when used under proper conditions, their misuse, particularly over a continued period, may lead to trouble. There has been no definite knowledge as to which of the many compounds may be suspected before use, and thus a clear need for research into the possible effects of every material that seemed open to suspicion. The subject is receiving study at the instance of the Association of British Chemical Manufacturers and the Home Office, which have referred the medical questions to a special committee of the Medical Research Council.

As a first step, a full summary of the available literature has been prepared by Dr. Ethel Browning. It deals with the hydrocarbon group, including such familiar substances as benzol and petrol, the large class of chloro-compounds which have found wide application, the alcohols, and particularly the esters, which are becoming of increasing importance. There follow cyclohexane derivatives, ketones and glycols.

The report will undoubtedly be of interest to the large body of makers and users. A difficulty with such materials is the well-known one that, whilst the makers and large users observe the necessary precautions, small users, who often buy their materials under a proprietary name, neglect to do so.

Sterols and Related Compounds:

a Series of Three Lectures delivered at the Institute of Biochemistry, Cambridge. By Prof. E. Friedmann. Pp. ix + 100. (Cambridge: W. Heffer and Sons, Ltd., 1937.) 7*s*. 6*d*. net.

PROF. E. FRIEDMANN is a distinguished visitor in our midst, and it was possibly this fact, rather than any novel features of his lectures, that caused his Cambridge colleagues to persuade him to reprint them in book form. The subject has, after all, already been covered at various lengths by Heilbron, Windaus, Fieser, Butenandt, Lettré and Inhofer.

However, the excellent reproduction of formulæ in this book and its condensed nature help to show the close relationships of the compounds discussed, and give it a certain quality of its own. Prof. Friedmann has mastered the English language very well, and, with the assistance of Mr. T. R. Parsons, has avoided all major solecisms. There are one or two minor inaccuracies that, should a second edition of this book be required, will demand attention. On p. 50 he has confused Windaus's vitamin D_1 and the English workers' original calciferol. On p. 65 is perpetuated the statement made by Prof. Friedmann elsewhere, that vitamin D_2 contains fewer international units per gram than calciferol. Actually, the two substances, when both pure, are identical in activity, as was shown by Schenck two months before this book was published.

Nevertheless, of the physiological relationship of the steroid group, including bile acids, heart poisons, saponins, antirachitic vitamins, sex hormones and carcinogenic substances, this book remains—errors and omissions excepted—a useful and readable survey. A. L. B.

Principles of Chemical Engineering

By Prof. William H. Walker, Prof. Warren K. Lewis, Prof. William H. McAdams and Prof. Edwin R. Gilliland. (Chemical Engineering Series.) Third edition, revised and rewritten. Pp. xi + 749. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 30*s*.

THE previous edition of this book has lasted a decade, a period during which chemical engineering has expanded enormously. New processes have been discovered, old ones improved, and a great deal of more accurate information has been established.

Dr. Walker, the initiator of the book, has passed away, and Dr. Lewis has taken little part in it, so that the work of preparing the new edition has fallen on the shoulders of the other two authors. The book has been fully revised, emphasis being placed as before on clarity in the presentation of the fundamental concepts. The most extensive changes are in the chapters on the flow of fluids and the flow of heat and on diffusional processes.

It will no doubt worthily replace the old edition on the shelves of the many who have found it of value.

Engineering

Combustion in the Boiler Furnace

By H. J. Hodsman. Second edition. (Leeds: Jowett and Sowry, Ltd., 1937.) 1*s*.

WHETHER the burning of coal in a boiler furnace shall be smoky or smokeless, or in other words, wasteful or efficient, is fundamentally a matter appertaining to the chemistry of combustion and, if the process is to be adequately understood by those employed in it, then, as a basis of rational practice, it is necessary that some effort should be made to elucidate the general principles. This has been recognized by the West Riding Regional Smoke Abatement Committee, which, as one of its activities, has established a scheme for the examination and certification of stokers and boiler attendants, for whom classes have been arranged by technical schools and colleges in the area.

The absence of suitable literature in a form and at a price to meet the needs of such students, led to the preparation of this booklet, which is issued with the approval of the Committee and has now reached a second edition embodying several alterations and additions. These deal more particularly with flue gases and the influence of their composition on efficiency, an aspect which presents some difficulty to this class of student. Beginning with an explanation of the combustion of carbon and hydrogen, in which chemical symbols and equations are freely introduced and simply interpreted, the author passes on to deal with the practical aspects of fuels and their combustion, describing from different points of view their composition and strongly emphasizing the magnitude and importance of the problem of air supply. At this point, the several methods of stoking are discussed and the influence of the character of the ash is referred to. The constitution of flue gases, the dependence of their volume and temperature upon the proportion of air supplied and the value of the carbon dioxide content are explained in straightforward terms. Their bearing on the operation and efficiency of the boiler and the practical considerations, which limit the best working proportion of carbon dioxide to a figure between 10 and 12 per cent, are set forth in terms which should readily appeal to a practically minded student.

The information presented here, in so clear and concise a form, is such as should be available in every boiler-room and in the possession of all responsible for the efficient combustion of coal, coke or other solid fuel.

Transient Electric Currents

By Prof. H. H. Skilling. (Electrical Engineering Texts.) Pp. xiii+349. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 25*s*.

THE title of this book, that of the series to which it belongs, and the first sentences of the preface, alike fail to convey a correct sense of the book's scope and aim. The preface says: "It is a book for engineers." This is only a partial truth; it is a text-book for engineering students (as indeed the preface goes on to explain), but it is not a handbook for working engineers and it is not a reference book. Much more is required before the author's hope that it "will help the student to attack any sort of transient problem with confidence" can be adequately realized. But as a text-book for students it is good; clear descriptions of the physical nature of transients take first prominence, the mathematical side being kept in its place as a necessary and important tool. Four introductory chapters are devoted to transients in simple series circuits of inductance, resistance and capacity. The next three deal with the indicial response of more complicated networks, the transient response to sinusoidal and non-sinusoidal voltages and transients in coupled resonant circuits. This last-named discussion is kept simple and illuminating by neglecting ohmic resistance. Then follows a chapter on solution of circuits with variable parameters by graphical and point-to-point methods. A clear exposition of travelling waves on non-dissipative and distortionless transmission lines leaves one to regret the serious omission of any discussion of standing-wave phenomena.

The last, and much the least satisfactory, chapter in the book gives a brief mathematical introduction to operational methods of analysis. Some faint breath of the fascination, the stimulation, the inspiration of these methods does penetrate the mathematic chill, but there is no illustration to suggest to the student the great power of these methods in the attack on otherwise difficult, laborious and intractable problems.

The book is well illustrated by figures, curves and oscillograms, and forms a good introductory text-book on the fundamental phenomena of transient electric currents.

Motion and Time Study

By Prof. Ralph M. Barnes. Pp. ix+285. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 18*s*. 6*d*. net.

THIS book by a professor of industrial engineering gives a comprehensive account of motion and time study from the days of the nineteenth century pioneers to the present day.

The large-scale development of many industrial operations during the last century has necessitated study of the most economical ways of doing the particular job, with the further object of determining the amount of work that should be done in a given period of time, and of fixing a wages scale.

The performance of manual work in an effective manner pre-supposes some understanding of the capacities and abilities of the human body. The writer reviews the work of Taylor and Gilbreth in this connexion, and shows how much later work is indebted to these early studies. He then applies the principles to various engineering operations and shows the use of these studies for the fixing of piece rates and wage incentives.

He avoids the error of believing that there is one best way that can be imposed on all workers, and he realizes that the output is affected by other factors than the method of the workers, for example, the conditions of lighting, heating, ventilation and vibration, and that the maximum comfort of the worker must be assured.

The whole book is written in a clear and systematic way, and it should be possible for the student of industrial psychology to apply these principles to very different operations.

Engineering Mechanics:

By Prof. S. Timoshenko and Prof. D. H. Young. Statics. Pp. xiv + 334.
Dynamics. Pp. xii + 323. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 15*s*. each.

THESE two volumes are intended by the authors to provide a thorough course in mechanics for the non-specializing engineering student. It is scarcely necessary, as one of the authors is so experienced a teacher as Prof. Timoshenko, to state that this aim has been well achieved.

Mechanics is a subject which can be really mastered only by the solution of a number of problems, and thus these two books contain instructive problems in abundance—more than three hundred in each volume (with answers), many of which are worked out in detail while for others hints are given as to the best method of attack. It is this well-selected collection of problems which will make these books valuable to the student. But he will probably also enjoy the text itself, which carefully and in simple language, and helped by a large number of excellent illustrations, leads him to the fundamental principles and to many of their interesting applications in modern engineering problems. A. B.

Television:

Theory and Practice. By J. H. Reyner. Second and revised edition. Pp. xi + 224 + 24 plates. (London: Chapman and Hall, Ltd., 1937.) 12*s*. 6*d*. net.

MR. REYNER'S revision of the 1934 edition has been extensive and entirely satisfactory. The television of 1937 is incomparably better than that of 1934, and this progress is fully represented in an edition in which every change has been an improvement. By discarding some descriptive matter, the author has, at the cost of some 15 per cent increase in length, and with substantial improvements in order and mode of presentation, given an up-to-date, accurate and absorbing account of present-day technique. It will appeal to a very wide range of readers, for the problem of combining accuracy, clarity and readability has been even more satisfactorily solved in this than in the excellent first edition.

Medical Studies

The Romance of Medicine

By Dr. John A. Hayward. Pp. xviii + 278. (London: George Routledge and Sons, Ltd., 1937.) 6*s*. net.

THE purposes of this little work, as we learn from the preface, is "to amplify the talks and lectures that have been given for King Edward VII's Hospital Fund, in the hope that it may stimulate interest in hospital work and public health". It is also hoped that it may be useful not only to young men and women who are thinking of taking up medicine, or nursing or allied professions, but also to older persons who wish to become acquainted with preventive measures against many diseases and the means of improving national health and physique.

The book is divided into two parts, devoted respectively to pre-scientific and scientific medicine. The first part consists of three chapters, in which ancient and modern medicine are compared, and a brief account is given of the surgery, midwifery, preventive medicine and tropical diseases in early times, and the deplorable conditions prevalent in the hospitals, which were notorious for their overcrowding and high mortality. The second part, which forms the bulk of the work, contains fifteen chapters, in which an excellent account is given of vaccination against smallpox, the discovery and later developments of anæsthetics, the germ theory of disease, with special reference to Pasteur, Lister and the antiseptic system, bacteriology, tropical diseases, biochemistry, vitamins, blood transfusion, physical science and medicine, Röntgen rays, radium and nursing.

The book is written in an easy style with occasional lapses into sentimental reflections, but we have found only three important omissions which might well be made good in a subsequent edition. In view of the not inconsiderable number of children and adolescents who become infected with venereal diseases, it savours somewhat of Victorian obscurantism to have omitted this important cause of ill-health, apart from a passing reference on p. 265, while the existence of alcoholism, with the exception of its prevalence among nurses prior to the advent of Florence Nightingale, and the remarkable improvement in the prophylaxis and treatment of mental disease, are not discussed.

With these reservations, we have nothing but praise for this little book, which deserves a wide circulation. The text is liberally interspersed with portraits, microphotographs, diagrams and other illustrations.

Blood Cultures and their Significance

By Hildred M. Butler. (Monographs of the Baker Institute of Medical Research, No. 3.) Pp. xiv + 327. (London: J. and A. Churchill, Ltd., 1937.) 15*s*.

A VERY complete survey of the subject of the cultivation of micro-organisms from the blood stream is given in this book. The method is one which is of considerable value as a diagnostic measure in certain diseases, and may be expected to throw light on various obscure disorders.

The history of the subject is dealt with in the first chapter, the technique of making blood cultures in the second, and interpretation of the findings in the third. In the remaining chapters, the findings in various diseases are described, and their significance is discussed, full bibliographies being appended to each chapter and at the end of the book. It is of interest how seldom micro-organisms seem to invade the blood stream in health—so infrequently that the few positive results obtained by the author (in only four of 106 individuals examined) might well be accidental contaminations. The author, in fact, is so sure of her methods that perhaps she scarcely stresses sufficiently the need for adequate skin disinfection in the technique adopted, and the possibility of aerial contamination of the cultures made.

This book has been compiled by one who has had great experience in this field of work, and the record of her investigations here presented must prove of much value to the clinician and clinical pathologist.

R. T. H.

Complement or Alexin

By T. W. B. Osborn. Pp. xi+116. (London: Oxford University Press, 1937.) 7*s.* 6*d.* net.

COMPLEMENT or alexin, present in fresh normal blood serum, is an 'agent' by means of which delicate specific tests may be performed for the laboratory diagnosis of many diseases and for the exact determination of various bacterial species. Although in daily use in the medical laboratory, and notwithstanding much research as to what it is, its exact nature still remains somewhat of a puzzle, and it has been variously regarded as being an enzyme, a manifestation of surface energy, a physical or physico-chemical state, a colloidal phenomenon. This book contains a most useful survey of the scattered but extensive literature upon complement and its action, and since Dr. Osborn has himself contributed to its study, he has been in a position to select the more relevant matter and to evaluate its trustworthiness. A bibliography, running into eleven pages, is appended. R. T. H.

Short Manual of Regional Anatomy:

Written for the Medical Student as an Aid to a Rapid Revision of the Whole Subject. By J. A. Keen. Pp. vii+167. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 5*s.* net.

THE author of this little work, who was formerly prosector and demonstrator of anatomy at King's College, London, deserves the gratitude of the student, whose labours he has done much to alleviate by his concise but lucid exposition. The English terminology adopted in 1933, in which eponymous nomenclature is omitted, is used throughout, but the older terms beloved of the medical historian are also given, and the Latin and Greek derivations, of which most students are ignorant, are appended to each chapter. The text is liberally interspersed with excellent figures and diagrams.

Appendicitis:

a Clinical Study. By W. H. Bowen. Pp. xii+202. (Cambridge: At the University Press, 1937.) 7*s.* 6*d.* net.

THIS little work, which Sir Arthur Hurst in his introduction declares to be the most satisfactory review of the subject in the English language, is based on the author's experience at Guy's Hospital and elsewhere. Special chapters are devoted to the etiology, diagnosis, prognosis, varieties of the disease, treatment and post-operative complications. A series of fifty-one cases is appended, classified in three groups according as the treatment was successful or unsuccessful, or other lesions were found at the time of the operation. The book should appeal alike to the physician, surgeon, general practitioner and senior student.

Miscellany

The Biology of Human Conflict:

an Anatomy of Behaviour, Individual and Social. By Dr. Trigant Burrow. Pp. xl+435. (New York: The Macmillan Co., 1937.) 15*s.* net.

IN this study of human behaviour the method and conditions of the inquiry upon which it is based are of no less interest and significance than the conclusions. The book is sponsored by the Lifwyn Foundation, a community formed for the purpose of this investigation at the instance, and under the inspiration, of the author. It consists of a number of individuals, male and female, socially and economically of varied but normal pursuits as ordinary citizens, who for sixteen years lived together as material for self- and communal-observation. The community was, in fact, the author's laboratory for the investigation of the fundamental causes which underlie the social maladjustments, of which insanity and criminality are among the most commonly encountered symptoms.

The point of view, or hypothesis, adopted by Dr. Burrow, which was thus submitted to examination, was based upon his previous experience of neuroses, suggesting that these and other evidences of conflict in behaviour are not abnormalities in a social environment which is predominantly sound, but indicate that the origin of the conflict is the elevation into a law of social conduct of the divorce between reality and the symbolism of the word by which reality originally was designated. The valid touchstone of behaviour is not the symbolism of the word, but the functioning of the organism as an integral whole. When, for example, the familiar dilemma of the relative character of the standards of good and evil is examined by an observer, who includes himself as material for observation and experiment, it emerges that, through symbolism, what is in fact secondary has been made the basis of judgment.

We Live and Learn:

Addresses on Education. By Sir Josiah Stamp. Pp. vii+214. (London: Macmillan and Co., Ltd., 1938.) 7*s.* 6*d.* net.

THE addresses printed in this volume cover a wide field. Consider their titles: graduation in social judgment, the management of mind, the limits of technical education, the development of post-primary education, education and the Christian view of the world, the tyranny and liberty of books, geography and economic theory, the institution in modern society, education and awareness. At first sight these nine themes appear unconnected. They turn nevertheless upon a three-fold conception of the aims and obligations of education, namely, that it should fit us to get a living, to live a life and to mould a world. If those aims, *in that order*, be accepted (and we doubt whether the acceptance is as widespread as the author believes) the link between the addresses becomes plain.

We hope the book will be read by educationists because it contains the kind of challenge they should expect when a mind as fresh and vigorous as Sir Josiah Stamp's examines their methods and purposes. His remark that he is "tired of people who pride themselves on their *general* ability and culture who have never been through the personal discipline of accurate and fine performance in some *particular*", might well be carefully studied by those to whom the word 'culture' represents something difficult to find in our modern industrial and commercial world. We hope, too, that the book will be read by scientific workers so that they may realize the danger to their own work if they lack awareness of the work of others, and of the interdependence of all branches of learning. J. W. M.

International Institute Examinations Enquiry

A Conspectus of Examinations in Great Britain and Northern Ireland. By Sir Philip Hartog, with the assistance of Grace Roberts. Pp. xiv + 182. (London: Macmillan and Co., Ltd., 1937.) 3*s*. 6*d*. net.

THE field (or jungle) covered by this bird's-eye view includes an amazing variety of tests applicable to examinees of all ages from ten upwards. The bird in question being Sir Philip Hartog, it is scarcely necessary to say that the view is comprehensive, keen, intelligent and lucid. It comprises (*a*) the Local Education Authorities', (*b*) the secondary school, and (*c*) the university examinations; also (*d*) those conducted under statutory authority for admission to professions or callings, and (*e*) a list of examining bodies classified under general subject headings—accountancy, advertising, aeronautics. . . . As regards (*a*), (*b*) and (*c*), the subjects of examination are set forth in detail. Incidentally, some light is thrown on methods. A glance through (*a*) shows that 'intelligence tests' are widely used as well as school records and interviews. In the university section, prominence is given to the growing practice of conferring degrees either wholly or partly for a thesis.

As regards (*d*) the various procedures adopted by Parliament in conferring authority to admit to certain callings are shown in brief without detailed lists of subjects of examination. This and the other publications ("English Bibliography of Examinations", "Examination of Examinations", "Essays on Examinations", "Marks of Examiners") of the Examinations Enquiry Committee (chairman, Sir Michael Sadler; director, Sir Philip Hartog) should be most helpful to all whose business it is to see that these multitudinous sifting processes function as beneficially as may be. The committee, and parallel committees in other countries, owe their existence to the International Institute of Teachers College, Columbia University and certain Carnegie endowments.

Science and Social Welfare in the Age of Newton

By Prof. G. N. Clark. Pp. vii + 159. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 6*s*. net.

A FACTOR in the growing concern of scientific workers with the social consequences of their work has been the realization that the extent of their work is itself largely determined by the nature of the society in which they work. In this interesting little study, Prof. G. N. Clark shows us, however, that this is no new phenomenon and that scientific progress was conditioned by the state of society as truly in the age of Newton as it is to-day. In a series of chapters dealing with science and technology, economic incentives to invention, the social and economical aspect of science and the social control of technological improvement, which represent the substance of four lectures delivered in the University of London in 1936, he gives a highly suggestive survey of the way in which not only has applied science influenced the whole structure of society but also science, and scientific methods, have been shaped and sharpened by what they took over from the arts and crafts and from the practice of merchants.

Prof. Clark traces five distinct groups of influence upon science, those from economic life, from war, from medicine, from the arts and from religion, all reinforcing or clearing the way for the sixth great motive, the disinterested love of truth, which it is the special social function of the universities to liberate from the pressure of other motives. In the final chapter he surveys the position of social science and shows that already at the beginning of the eighteenth century it appeared to have an established position and a great future. His little volume appears at an opportune moment and has claims on the interest of all those scientific workers who are concerned with the increasing co-operation of science and economic life. R. B.

Philosophy and Psychology

The Human Situation:

the Gifford Lectures delivered in the University of Glasgow, 1935–1937. By W. Macneile Dixon. Pp. 438. (London: Edward Arnold and Co., 1937.) 18*s*. net.

HOWEVER difficult and technical philosophy may be to-day, its purpose is still practical: knowledge and happiness are and remain fundamental urges of man, which cannot be brushed aside by a simple pronouncement of modern science that man is completely unimportant in the economy of the world. The only way to replace philosophy in that lofty station it should occupy in our interests, is to bring it back to the market place without stripping it of its academic dignity. This Prof. Dixon does with conspicuous success. In keeping with the intentions of the founder of the Gifford Lectures, the author discusses the evolution theory, personality, responsibility and determinism, relativity, quantum mechanics, original sin, Christianity and Buddhism, and all the major problems of thought and conduct in a 'popular' manner, by using words of daily speech in the sense to which we are all accustomed and with the purpose of being more easily followed.

The philosophical attitude of the author, which approximates that of Leibniz, makes his attempt the more sympathetic; while his co-ordination and criticism of the views held by philosophers, theologians and scientific workers, give his work an outstanding importance for our time, which suffers too much from extreme specialization.

T. G.

A Critical Exposition of the Philosophy of Leibniz: with an Appendix of Leading Passages.

By Bertrand Russell. Pp. xxiii+311. (London: George Allen and Unwin, Ltd., 1937.) 12*s*. 6*d*. net.

THE philosophy of Leibniz has achieved considerable importance in recent years, on account of the growth of mathematical logic, which is considered to be a development of it. Hence the interest of Russell's critical exposition of the great philosopher's views, and the justification for this second issue of the work. Though a reprint of the first edition (1900), the present book contains a preface in which Russell takes stock of Leibnizianism and points out where his own ideas now differ from those he held nearly forty years ago. In spite of the publication, in the meantime, of a wealth of small scripts of Leibniz which necessitate a readjustment of his views on some details, Russell finds little cause for altering his original estimate of the philosophy of Leibniz—an admission which gives an added interest to the re-issue of his masterly monograph.

Visual Perception

By M. D. Vernon. Pp. xi+247. (Cambridge: At the University Press, 1937.) 15*s*. net.

THIS monograph gives for the first time in a single volume a comprehensive and detailed account of the numerous experimental investigations that have been carried out on the nature of visual perception. It has been Miss Vernon's aim in this book to present a treatment of the subject as exhaustive as possible, while avoiding preconceived bias towards one or another hypothesis, and to record the essential results that emerge from the experimental work. The development of the process of perception, the relations between percept and observer and percept and object, and the development of perception in children, are dealt with in turn, and the work of the Gestalt school of psychologists is fully considered. An appendix contains descriptions of the most generally used tachistoscopes, and references to some four hundred publications consulted in the preparation of this monograph are contained in the bibliography.

Physics

An Introduction to Modern Thermodynamical Principles

By A. R. Ubbelohde. Pp. viii+132. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 8*s*. 6*d*. net.

A SERIES of lectures delivered in the Department of Thermodynamics at Oxford forms the basis of this book. The contribution which the Clarendon Laboratory has made to chemical thermodynamics is widely known, and the author has performed a valuable service in presenting the points of view of this school in such a readable form.

Nernst's theorem was probably better understood, in its early days at least, on the Isis than on the Cam: we find an adequate account of its successes and failures, though one might hesitate to subscribe wholeheartedly to the opinion—expressed in the preface—that thermodynamics is an essentially practical science. Carathéodory in his "Grundlagen" presumably thought much needed doing before that condition could be realized. The experimentalist, however, is often in a state of partial confusion between the various thermodynamic functions and the uses to which they may be put in the study of equilibria. This volume disentangles them with exceptional lucidity, and their practical value is always before the reader.

The discussion of the specific heat of solids follows conventional lines; it might, perhaps, have been more valuable if at least a mention had been made of Schaefer's analysis, which showed that in the immediate neighbourhood of the absolute zero Debye's T^3 law cannot be valid, and that a transcendental expression is demanded. Completeness apart, this result is exceedingly interesting on its own account as an example of the application of the theory of functions to a physical problem.

The chapters dealing with statistical mechanics are very well done, and give exactly the right amount of information, with no needless elaboration.

F. I. G. R.

Thermodynamics

By Prof. Enrico Fermi. (Prentice-Hall Physics Series.) Pp. x + 160. (New York: Prentice-Hall, Inc.; London and Glasgow: Blackie and Son, Ltd., 1937.) 3 dollars; 7*s*. 6*d*. net.

PROF. FERMI'S treatise is not so specialized as might be imagined from the fact that it is a development of a course of lectures given in 1936 at the Columbia University. It is classical in outlook and quite elementary in treatment, beginning with a close consideration of the definition of a thermodynamical system, about half the book being concerned with chapters on the first and second laws of thermodynamics and entropy.

A useful chapter on thermodynamic potentials where free energy is defined as $U - TS$ and the function $U - TS + pV$ is the thermodynamic potential at constant pressure, contains a clear, if condensed, treatment of the phase rule and the thermodynamics of the reversible cell. The two following chapters deal with gaseous reactions and with the thermodynamics of dilute solutions. The concluding chapter on the entropy constant and the Nernst theorem contains a few hints of quantum mechanical concepts.

The book is inexpensive and will form a useful addition to the shelves of the student of physics or physical chemistry. A. F.

Properties of Matter

By D. N. Shorthose. Revised edition. Pp. viii + 168. (London: William Heinemann, Ltd., 1937.) 4*s*.

THE author intends this book for higher school certificate and scholarship examinations. In the section on dynamics the general relations of mass and motion are assumed, as the book begins with a chapter on circular motion, followed by one on simple harmonic motion. It is doubtful whether the use of initials in place of the names of quantities is really an advantage. A few are, of course, well recognized, such as E.M.F. and H.P., but the use of M.I., P.E. and K.E. is questionable.

The chapter on gravitation follows the usual lines, but the fact that the attraction of a uniform sphere is the same as that of an equal mass at the centre is assumed. The chapter on surface tension is particularly good. Then follow friction and elasticity, omitting beams.

In the second edition a chapter on viscosity has been added for the sake of completeness. Throughout the book are numerous worked examples, and at the end of each chapter is a set of examples which the student will find extremely useful.

Travel

Stepping Stones from Alaska to Asia

By Isobel Wylie Hutchison. Pp. x + 246 + 20 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1937.) 12*s*. 6*d*. net.

THIS makes no pretensions at being a scientific compilation; it is merely "a little record of a happy summer". Nevertheless, it will delight the scientific worker with a taste for semi-adventurous travel not only because of its breezy narrative and vivid descriptions of new and noteworthy features offered by a little-known part of the world, but also because of the highly commendable (and unfortunately quite unusual) care with which the author has followed the dictates of specialists who have worked in the region concerned. This region is, primarily, the Alaskan-Aleutian Chain, which extends in graceful curve but treacherous seas nearly 2,000 miles westwards from north-west America towards Asia. Such notes as we are given on its flora and ethnology are right up to date, the theorizing being correspondingly restrained, with the result that we are presented with a record which will be of definite value to all who are interested in the life and surface features of the North Pacific.

The few small blemishes are in most cases unwarranted generalizations concerning other parts of the globe. Thus some places spoken of as being in northern Greenland are in reality far south on that great 'continent', even if their district is known to the inhabitants as "North Greenland", while the reviewer has seen Greenland (and also Baffin) Eskimo devour ravens with marvellous dispatch, and has even joined in the feast with no ill-effect or hint at a 'taboo'; he has also found *Spiranthes Romanzoffiana* growing wild in many places much nearer to the British Museum than Alaska or even Hudson Bay!

The author is an energetic Scottish woman, apparently of middle-age—an ardent and experienced, if technically untrained, botanical collector—with grit and perseverance as outstanding attributes. Now here lies a poignant indication; she has recently visited several of the least accessible regions in the world alone and without 'expedition press' or acclamation as a 'heroic explorer', which suggests once more that the epoch of such things and people is drawing to its natural close, and that its place is being taken by one of serious scientific investigation and honest travel.

N. P.

The Black Musketeers:

the Work and Adventures of a Scientist on a South Sea Island at War and at Peace. By A. J. Marshall. Pp. xiii + 329 + 35 plates. (London: William Heinemann, Ltd., 1937.) 15*s*. net.

MR. MARSHALL'S "Black Musketeers" are the Melanesian inhabitants of Espiritu Santo, the most northerly island of the New Hebrides group. The name by which he calls them is not so fanciful as it may seem. Their characteristic weapon, once the bow, is now the old Snider musket, a relic of the mid-nineteenth century.

Mr. Marshall, a young Australian, who had already won his spurs as an explorer and ornithologist on his own continent, joined Mr. Tom Harrisson, a member of the Oxford University Exploration Club's expedition to the New Hebrides. He was left behind by the expedition for a further year's observational work on the causes of a breeding season in animals and plants. The subjects of the investigation were birds, bats and lizards, of which specimens were collected for dissection at stated periods throughout the year. Meteorological observations were made and recorded daily. The routine work was certainly strenuous; but nevertheless the two colleagues had ample opportunity, as is shown in "Savage Civilisation", the book by Mr. Harrisson covering the same period, to make friendly and in some instances intimate contacts with the natives. Their most exciting adventure here recorded was an inter-village war, in which they barely escaped being involved; while a hurricane provided its share of thrills by partially wrecking their camp. Mr. Marshall is no less strong than Mr. Harrisson in his condemnation of the English-French condominium; but the work of the missionaries, however much it may have been misdirected in the past, is now accorded its meed of praise.

New Fellows of the Royal Society of Edinburgh

At the ordinary meeting of the Royal Society of Edinburgh, held on March 7, the following ordinary members were elected: Mr. C. H. W. G. Anderson, head master and superintendent, Royal Blind School, Edinburgh; Dr. P. Bacsich, lecturer in human embryology, University of Glasgow; Dr. D. A. Bannerman, unofficial scientific worker, Department of Zoology, British Museum (Natural History); Mr. A. W. M. Beveridge, treasurer, Bank of Scotland, Edinburgh; Dr. G. B. Brook, district veterinary officer, County Council of Staffordshire; Mr. C. A. Carlow, managing director, Fife Coal Co., Ltd.; Sir Ian Colquhoun; Prof. M. M. Cruickshank, Madras Medical College, Madras; Mr. S. Cursiter, director, National Galleries of Scotland, Edinburgh; Dr. J. M. Dewar, Edinburgh; Mr. N. McOmish Dott, neurological surgeon, Edinburgh; the Right Hon. Lord Elphinstone; Mr. C. H. P. Gifford, Edinburgh; Dr. Cecil Gordon, lecturer in genetics, University of Aberdeen; Dr. W. S. Gordon, chief bacteriologist, Moredun Institute, Animal Diseases Research Association, Gilmerton, Midlothian; Dr. R. Kumar Goyal, research worker, School of Tropical Medicine, Calcutta; Dr. J. R. C. Greenlees, head master, Loretto School, Musselburgh; Mr. G. Hogarth, chairman, Fishery Board of Scotland, Edinburgh; Mr. J. D. H. Jamieson, lecturer in dental diseases, University of Edinburgh; Dr. A. M. MacGillivray, lecturer in clinical ophthalmology, University of St. Andrews; Dr. Alexander Mackie, science master, Trinity Academy, Edinburgh; Prof. W. H. McMillan, Hood professor of mining, University of Edinburgh and professor of mining, Heriot-Watt College, Edinburgh; Prof. Donald Mainland, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia; Dr. C. A. Malcolm, librarian, Signet Library, Edinburgh; Sir John Maxwell Stirling Maxwell; Prof. H. H. Monteath, Conveyancing Department, University of Edinburgh; Dr. S. S. Munro, geneticist, Dominion Department of Agriculture, Ottawa; Prof. T. C. Phemister, Department of Geology, University of Aberdeen; Dr. A. M. Ramsay, formerly lecturer in ophthalmology, University of Glasgow; the Right Hon. Earl of Rosebery, lord lieutenant of Midlothian; Mr. J. Sandilands, lecturer in chemistry, Heriot-Watt College, Edinburgh; Mr. A. H. H. Announcements

The Institute of Metals Medal "for outstanding services to non-ferrous metallurgy, whether on the practical or scientific side" was awarded to Sir William Bragg at the annual meeting of the Institute held on March 8.

The Bessemer Gold Medal for 1938 of the Iron and Steel Institute has been awarded to Dr. C. H. Desch, superintendent of the Metallurgical Department, National Physical Laboratory, Teddington.

The Keith Prize, for the period 1935–1937, of the Royal Society of Edinburgh has been awarded to Prof. H. S. Ruse, professor of pure and applied mathematics in University College, Southampton, for his paper "On the Geometry of Dirac's Equations and their Expression in Tensor Form" published in the *Proceedings* of the Society within the period, and for his other papers in the *Proceedings*.

At the sixtieth annual general meeting of the Institute of Chemistry, held on March 1, Sir Robert Pickard was re-elected president. The Meldola Medal for 1937 was presented to R. P. Bell, of Balliol College, Oxford, and the Sir Edward Frankland Medal and Prize was awarded to L. Smith, of the Sir John Cass Technical Institute.

Prof. Viktor Müller-Hess, director of the Institute for Forensic and Social Medicine in the University of Berlin, has been nominated a corresponding member of the Portuguese Academy of Sciences.

The Associated Voluntary Hospital Board has appointed a commission under the chairmanship of Dr. Arnold D. McNair to report on the investigation and treatment of cancer in the Liverpool area, and on the possibility of extending and improving the work. Particular attention is to be paid to the best way of using and co-ordinating the available hospital and research facilities. The Commission is also to decide whether a change is needed in the organization, policy or construction of a Liverpool radium institute and hospital for cancer.

The British Council has instituted twenty post-graduate scholarships, each of the value of £250, to enable foreigners who have graduated in their own country to pursue a year's specialized study at a British university. The scholarships have been allocated on the basis of either one or two for each of 14 countries. A wide choice of subjects is given, and include architecture, agriculture, engineering, trade, sociology, aviation, forestry, journalism, law, shipbuilding, textiles, Oriental languages, history, and English language and literature.

Erratum. After having been approved by the authors and finally passed for press, the block for the diagram illustrating the communication by Dr. J. B. Speakman and E. Stott in Nature of March 5, p. 414, was unfortunately inverted. The axes of the figure are, of course, correct; but the graphs should be inverted in relation to these axes.

Letters to the Editor

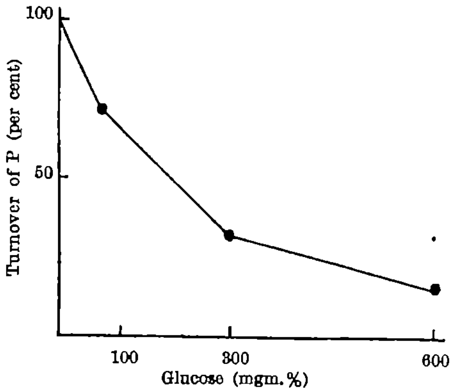
The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 476.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Glycogen Breakdown in Muscle Extract and Yeast Juice

IT has been shown that the transport of phosphorus (P) between creatine and adenylic acid in muscle extract (Lohmann's reaction and its reversal) can be expressed as a chain of equilibria obeying the laws of thermodynamics and controlled by the pH[1,2]. Parnas and Ostern and their schools[3,4], have recently described another case of phosphorus transport in muscle extract in the formation of hexosemonophosphate from inorganic phosphate and glycogen. It appeared of interest to study the kinetics of this reaction.



INHIBITION OF GLYCOGEN BREAKDOWN BY GLUCOSE IN MUSCLE EXTRACT. 1 C.C. OF 10 DAYS OLD MUSCLE EXTRACT (AFTER MEYERHOF) FROM RABBIT + 2 C.C. ADDITIONAL SUBSTANCES CONTAINING 10 MGM. GLYCOGEN; 1·15 MGM. P AS PHOSPHATE BUFFER, pH 7·2; 200γ ADENYLIC ACID AS SODIUM SALT. 100 PER CENT TURNOVER WAS 0·51 MGM. P OF HEXOSEMONOPHOSPHATE FORMED.

It was first of all of interest to find that dialysed extract of yeast to which yeast adenylic acid was added behaved exactly like muscle extract; it phosphorylated only glycogen and not glucose. Willstätter and Rohdewald[5] showed that living bottom yeast condenses glucose to glycogen before phosphorylation occurs.

The reaction reaches in muscle extracts and yeast juice alike an equilibrium which may be expressed by the following equation, in which water cancels out and glycogen may be described sufficiently for this purpose as hexoseanhydride (n hexose $-$ ($n-1$) H_2O):

$$\frac{\text{Mol. Hexosemonophosphate}}{\text{Mol. Hexoseanhydride} \times \text{Mol. Phosphate}} = K \times 10^{-3}$$

At 37° and pH 7·2, K was between 0·02 and 0·08 and of about half that value when starch was used instead of liver glycogen. Hexosemonophosphate, the product of the reaction, inhibits esterification of glycogen. Of more general interest is the observation that the glycogen breakdown can also be suppressed by glucose.

The braking effect of glucose on glycogen decomposition is 50 per cent at a concentration equal to that of the sugar level in normal blood, and nearly vanishes at a concentration corresponding to hypoglycæmia *in vivo*.

Two suggestions may be made which account for these observations with muscle extract.

(a) Lactic acid formation from glucose (which needs no inorganic phosphorus and has glutathione as coenzyme) may be different[6] in its physiological meaning from the lactic acid formation from glycogen (which needs phosphorus, magnesium, adenylic acid and cozymase). The former reaction, prevailing, for example, in brain (Ashford and Holmes[7]), and in the embryo (Needham and Nowinski[8]) would serve for continuous functioning and would be kept up steadily by the glucose level of the blood. The latter reaction, most pronounced in skeletal muscle, would act as a reserve and increase the lactic formation, acting discontinuously as a 'second wind' where sudden heavy demands on the blood sugar cause local hypoglycæmia.

(b) Secondly, the phenomenon observed may help to make intelligible the mechanism of hypoglycæmic convulsions. Sudden increase in breakdown of muscle glycogen, which is connected with muscular contraction, should occur when the blood sugar is low. These convulsions are already known to be independent of the brain as they can occur in the decapitated animal[9], where a dehydration of the blood takes place which, as Olmsted and Taylor[9] have described it, "could be due to increase in molecular concentration within the tissue itself". Excess of hexosemonophosphate, a very active oxygen acceptor, could account further on for the extreme deoxygenation observed by the same authors in hypoglycæmic blood which in the arteries was already of venous appearance. Hypoglycæmic convulsions in insulin shock depend in their intensity on the previous diet of the experimental animal, and they are much more marked after a diet rich in carbohydrate (Abderhalden and Wertheimer[10]). This should lead to glycogen storage in the tissues.

Magnesium and Calcium Content of Hedgehog Serum during Hibernation

OUR knowledge of the mineral metabolism of hibernation is still very meagre. I have therefore investigated, among other questions, the magnesium and calcium content of hedgehog serum. Part of the animals were analysed in early October, about four to five weeks before the final onset of hibernation, and others in early January when the hibernation was at its deepest. Calcium was determined by Kramer and Tisdall's method; magnesium was precipitated as magnesium ammonium phosphate according to Rappaport[1], and the phosphorus was determined colorimetrically with a Zeiss Pulfrich-photometer according to the amidole method of Müller[2].

In autumn, before the onset of hibernation, the magnesium content of the hedgehog serum averaged 3·20 mgm. per cent. The series comprised seven animals, the magnesium content varying from 2·90 to 3·55 mgm. per cent. The calcium content of the serum of these animals averaged 10·0 mgm. per cent, with variations ranging from 9·2 to 10·6 mgm. per cent. The average ratio calcium to magnesium was 3·15.

In the beginning of January the hedgehogs were in deep hibernation. The magnesium content of the serum then averaged 5·43 mgm. per cent. The series consisted of six animals, the variations in the magnesium content being 4·90–6·05 mgm. per cent. The calcium content in the serum of these animals averaged 10·2 mgm. per cent, varying from 9·6 to 10·7 mgm. per cent. The average ratio calcium to magnesium was 1·88. It is seen that the magnesium content of the hedgehog serum has increased considerably during hibernation. In the above experiments, the magnesium value during the deepest hibernation in mid-winter was 170 per cent of the corresponding value in autumn, before the onset of sleep. On the other hand, the calcium content remains constant. This causes a decrease in the ratio.

It seems that the increase of the magnesium content of the serum during hibernation is an important phenomenon in general biology. Lustig, Ernst and Reuss[3] have recently shown that there is a considerable increase also in the magnesium content of the blood of Kursiv during winter torpor. It is known that the most striking effect of the magnesium ion is its power to produce anæsthesia. It has an anæsthetic effect on several invertebrates of sea and fresh water and, as shown already by Meltzer and Auer[4], also on vertebrates. The anæsthesia disappears if some calcium is injected into an animal previously treated with magnesium. In view of these results, it is interesting to note that, according to my determinations, there is not only an increase in the magnesium content of the serum of the hibernating hedgehog, but also a considerable change in the ratio calcium to magnesium.

A Contradiction in the Present Clearance-Reabsorption Views of Urea Excretion

BEYOND a certain rate of urine flow, for man, dog, rabbit, etc., and provided the blood concentration does not exceed a concentration of about 200 mgm./100 ml., the following equation holds approximately:

$$\frac{\text{Output of urea}}{\text{Blood conc.}} = \text{constant},$$

and has been chiefly demonstrated by the work of Addis and Drury[1]. The constant of this equation has been interpreted as a volume of blood per minute by Van Slyke and Peters[2] and called a 'clearance', since it has also the dimensions of a volume. The interpretation is here particularly unsafe since a much better equation applying over the whole range of urine volume gives a constant with no such dimensions (a diffusion pressure equation).

The explanation given of the constancy is that there is a constant filtration rate at the glomerulus and that variations in the urine volume excreted are almost altogether due to different volumes of water reabsorbed. Since, however, the inulin clearance is about twice that of the urea[3] and inulin is not regarded as actively excreted by tubular action, it must necessarily follow that about half the glomerular output of urea is reabsorbed in the passage through the tubules. It is this view that contains an inherent contradiction.

To demonstrate this, we may suppose that the subject (human) is excreting at a rate of 200 ml. urine per hour and at a blood urea concentration of 20 mgm./100 ml., this being achieved by water drinking. After the water diuresis has passed, urea is administered so that the blood concentration reaches 80 mgm./100 ml. and the urine rate again reaches 200 ml. per hour. There is now a general agreement that—at least within 10 per cent—the average clearance value will be the same as before. This can only mean on the above view that four times the amount of urea is being reabsorbed back across the tubule, and hence the conclusion that urea is reabsorbed back in proportion to its lumen concentration is inevitable.

It may then be supposed that the subject drinks water so that his urine rate reaches 800 ml. per hour. The clearance will remain unchanged, so that the amount of urea reabsorbed is the same as before, but at the same time the lumen concentration has fallen to upwards of one fourth its previous value, from which we may conclude in turn that the back absorption of urea is independent of its lumen concentration. This contradicts our previous conclusion.

Put in another way, it may be said that from the present clearance-reabsorption views, the excretion of urea or urea clearance should rapidly and asymptotically approach that of inulin beyond a urine rate for the human subject of about 120 ml. per hour. Of this it may be said with certainty there is no sign; since even if recent work[4] has shown a rise in the urea clearance with increasing rate, it goes parallel to the inulin clearance, which has been regarded as a standard for measuring the glomerular filtrate.

Decomposition of Organic Peroxides

IN order to study the influence of peroxides on the oxidation of hydrocarbons and to discover the part they play in the phenomenon of ignition, the mode of their decomposition and oxidation is being further investigated. It has been found by Neumann[1] that diethylperoxide decomposes with luminescence above pressure limits (p_0) which are connected with temperature according to the relation $\log p = A + B/T$. We find that A and B depend on the dimensions of the vessel in which the decomposition occurs. Up to the neighbourhood of the sharp pressure limits the peroxide decomposes unimolecularly with an activation energy 34 kgm. cal. The influence of foreign gases (such as helium) on the pressure limits appears to be small, and similar to the behaviour of such gases on the decomposition of azomethane[2].

Meteoric Ionization in the *E* Region of the Ionosphere

IN a letter which recently appeared in these columns[1], T. L. Eckersley described the discovery of great numbers of short-lived ionic clouds in the upper atmosphere. He suggests that the responsible agents might be small meteors or high-speed particles of cosmic origin. His data support the assumption of a meteoric origin so strikingly as to warrant special emphasis.

These clouds appear in the *E* region of the ionosphere in which meteors are known to spend most of their energy and from which most of the meteoric reflections of radio waves have been obtained. They are apparently short-lived isolated clouds in which momentarily the ionization reaches a value much higher than the average. This is precisely the sort of thing to be expected from the passage of a small meteor. Since a very bright one (−1 mag.) left sufficient ionization to reflect 180 metre waves for 7 minutes after its passage[2], the short period (of the order of a second) during which reflections are received from these clouds is consistent with their magnitudes. For since there are many more of these clouds than there are meteors as seen by a single observer, the meteors producing them must be fainter than the sixth magnitude on the average.

On the basis of telescopic observations, it has been estimated[3] that 10^9 meteors (of eighth magnitude or brighter) enter the earth's atmosphere every twenty-four hours. One should thus expect about 180 such meteors in an area 500 km. in diameter in 40 seconds. Eckersley found for these conditions about 30 ionic clouds or 1/6 as many as the estimated number of meteors. The agreement is as good as could be expected considering the nature of the phenomenon.

Even ultra-short waves which are not ordinarily reflected by the ionosphere might be expected to suffer reflection by ionic clouds of meteoric origin. L. F. Jones[4] has reported observations on such waves which might have this same primary cause. Regarding television signals, which are not ordinarily received with usable field strength at the long distance over which he was working (284 miles), he states: "Sometimes the signal would burst through sharply for a short period . . . ," and again, "the signal . . . reaches momentarily an occasional maximum of great intensity".

Ionic clouds of meteoric origin must be discrete regions in which the ionization is very dense. The rate of recombination would therefore be high and the life of the clouds would be short. This reasoning is consistent with the observed short duration of reflections and again points to the meteoric origin of Eckersley's clouds.

Disintegration Processes by Cosmic Rays in Plates impregnated with Samarium

Blau and Wambacher[1] have recently described experiments in which it appears that a novel type of disintegration may be provoked by cosmic radiation. 'Stars' of tracks due to heavy particles were found in plates which had been exposed for some months at a high altitude. For two years we have been conducting experiments of the same type. We find stars of a similar kind, but there are important differences between our results and those of the Vienna workers, which are indicated below.

The experiments were commenced with the view of discovering whether the cosmic radiation has any influence on the radioactivity of samarium. Ilford *R* plates were used, and samarium was incorporated into the emulsion by soaking part of the area of each plate in a solution of samarium sulphate. After exposure and development the boundary of the impregnated area is visible on the plate. After preparing a number of plates in this way they were sealed in a small box, along with untreated plates for subsequent comparison. One such box of plates was kept for five months, May–September, at Gulmarg in Kashmir (latitude 34° N.). A similar box of plates was kept for an equal period in Bombay, being placed in a refrigerator to avoid the deleterious effects of the high temperature. After allowing for the thickness of the packing and the roof of the building, it may be assumed that the Kashmir plates were at an equivalent height of 8,000 ft. above sea-level. The Bombay plates were practically at sea-level.

In the first set of experiments carried out in 1936, some stars of tracks were found. The plates, however, were unfortunately rather poor, and we were not able wholly to exclude the possibility of some radioactive contamination. The experiments were therefore repeated in 1937, taking every possible precaution. This time good plates were obtained, which have yielded the following results.

(1) Both in the Bombay and Kashmir plates, we find practically no tracks in the untreated plates, nor in the blank areas of the treated plates. The only tracks found are those due to the natural radioactive content of the glass, such as were described in an earlier paper[2]. This result contrasts with that

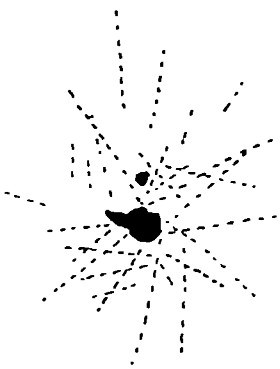
of Blau and Wambacher, who find stars in untreated plates. The difference may possibly be traced to the different sensitivity of the plates employed.

(2) In the treated areas of both Bombay and Kashmir plates, numerous tracks are found which are due to the short-range α-particles which are emitted by samarium. The number of such tracks gives a convenient indication of the quantity of samarium incorporated into the emulsion. The tracks of longer range, previously ascribed to protons[3,4], are also observed, with much the same relative frequency as in previous experiments.

(3) Numerous stars are found in the treated areas of the Kashmir plates. These stars comprise from two to six tracks. (It may be noted that contamination by radiothorium would only give stars of five tracks[5].) The ranges and directions appear to be distributed at random, and the maximum ranges do not exceed 5 cm. of air.

(4) The treated areas of the Bombay plates are apparently almost free of stars. Further search has still to be made, but in the considerable area already examined only one star has been found. In any event their relative frequency, as compared with the stars in the Kashmir plates, must be well below 1 : 100.

(5) We observe, in the treated areas of the Kashmir plates, but not in the Bombay plates, a phenomenon of an apparently different kind which we call a 'cluster'. This is best indicated by the accompanying sketch. Numerous tracks, up to about 40 in number, emerge from a limited area, but not from a point. Twelve such clusters have been observed. It has been pointed out previously[2] that *R* plates occasionally show a single very large grain of silver bromide, which appears on the developed plate as a black area having a diameter of perhaps 10 μ. We find that such a large grain is situated in the central region of seven out of the twelve clusters. As the large grains are relatively rare, it is clear that this cannot be fortuitous, and we must therefore conclude that the clusters, or some of them, are associated with the presence of silver or bromine.



(6) Both in the stars and in the clusters the individual tracks appear to be due to protons, judging by the density of grains along the track, but we cannot be certain of this conclusion.

It is perhaps premature to offer any interpretation of these results, of which we hope to publish a fuller account elsewhere. Further experiments are in progress.

Factors influencing Stability of Superlattices

In metallic solid solutions atoms of the different elements are usually distributed at random throughout the lattice. In certain cases, however, an ordered distribution, or superlattice occurs. The transformation from order to disorder has received considerable attention because the simplicity of the process renders it susceptible to theoretical interpretation. The entropy change is practically equal to the entropy of mixing, which can be calculated from first principles. The ordered state, which has the lower entropy, will be stable only when its internal energy is lower than that of the disordered configuration.

Two factors influencing the energy of ordering have been recognized, namely, forces between neighbouring atoms and lattice strains due to differing atomic sizes. It has not been emphasized, however, that both factors operate simultaneously. In the ordered state, atoms tend to be surrounded by foreign atoms. Hence attraction between unlike atoms stabilizes the superlattice. Hume-Rothery and Powell[1] point out the second factor that lattice strains due to differing atomic sizes will be less in the superlattice. The energy of ordering is thus due partly to interactions between neighbouring atoms and partly to geometrical strain. The latter factor is predominant in chemically similar atoms.

It occurred to us that these factors could be separated in studying the effect of silver on the gold-copper superlattice. When some of the gold atoms are replaced by silver atoms, which are practically the same size, the geometrical factor remains constant. Any change must be due to difference in attraction between neighbours.

The fifty atomic per cent gold-copper superlattice is most suitable for study since a change of symmetry, easily detectable by X-rays, occurs when the lattice becomes ordered. In the disordered state each gold atom has on the average six copper and six gold neighbours, while in the ordered state there are eight copper and four gold neighbours. The non-geometrical part of the energy of transformation is due to the breaking up of gold-gold and copper-copper pairs to form gold-copper pairs.

$$\mathrm{Au:Au} + \mathrm{Cu:Cu} = 2\,\mathrm{Au:Cu}$$

Silver atoms substituted for gold should go into the gold superlattice positions, and part of the above process now consists in the breaking of silver-gold pairs to form silver-copper pairs.

$$\mathrm{Ag:Au} + \mathrm{Cu:Cu} = \mathrm{Ag:Cu} + \mathrm{Au:Cu}$$

Deviation from Vegard's law of additivity of atomic radii has been proposed as a measure of forces between atoms in alloys[2]. Strong attraction should result in pulling atoms closer together, resulting in a negative deviation from Vegard's law, while positive deviation indicates a weak attraction. In the absence of direct measurements of heats of reaction, this is our best criterion.

Accepting deviation from Vegard's law as a measure of forces between atoms, the results of the above experiment may be predicted with confidence. Silver-gold has a negative deviation, indicating strong attraction, the copper-gold deviation is positive indicating weaker attraction, while the silver-copper attraction is weakest of all. Hence it is more difficult to break the strong silver-gold pairs to form the weak silver-copper pairs in the ordering process represented by the second equation above than to carry out the corresponding process in the first equation. Silver should thus decrease the stability of the superlattice, lowering the transformation temperature.

Our experiments give the predicted results. As silver is substituted for gold, the transformation temperature gradually decreases. For example, in an alloy of 46 atomic per cent gold, 4 silver, and 50 copper the transformation occurs near 360° C., while in the 50 gold-50 copper alloy the transformation temperature is considerably higher, best reports[3] placing it near 425° C.

Since the energy of ordering can be approximately calculated from the transformation temperature and the entropy change, this furnishes a semi-quantitative comparison of the energies of interaction between the pairs concerned.

We are also determining accurately atomic volume and axial ratios at different annealing temperatures. We confirm the existence of the orthorhombic phase reported by Johansson and Linde[4] and find that it persists after long periods of annealing at temperatures lower than they report. We hope to publish the complete results elsewhere after our work is concluded.

Some Observations on the Rotating Pendulum

WHEN a simple harmonic pendulum is viewed binocularly with a neutral-tint filter in front of one eye, the pendulum, instead of swinging to and fro in a plane, appears to swing in an ellipse, first advancing towards and then receding from the observer[1]. The simplified but not quite true explanation of the illusion is that the 'latent period' of vision in the unobscured eye is shorter than that in the other eye, the brighter retinal image being followed by the shorter latent period. If with a pendulum swinging from right to left, both eyes fixate the true position in space of the pendulum, then the right eye will project the pendulum along a line to the right of the line of fixation whilst the left eye if obscured will project it along a line still more to the right of its line of fixation. The lines of projection will intersect at a point on the observer's side of the pendulum and this is the position in space which the pendulum will appear to occupy. Similarly it can be shown that the pendulum will appear to recede from the observer when passing from left to right and that its point will trace out an ellipse. Using a movable pointer beneath the pendulum, an observer can measure the apparent forward displacements with filters of varying densities in front of one eye and it is possible to calculate the difference in time (sec.) between the latent periods of the two eyes (ΔLP) for any given ratio between the retinal illuminations of the two eyes (I_u/I_o). I find that the relation is $0{\cdot}02 \log_{10} I_u/I_o = \Delta LP + c$, where c is a small constant depending on the difference between the latent periods of the unobscured eyes. The relation holds accurately for any one illumination of the pendulum, but with any given filter ΔLP becomes smaller if the illumination is considerably increased.

With the filter in front of the right eye the pendulum will seem to swing anti-clockwise, and provided the eyes are treated alike in other ways, we are probably justified in saying that because the right retinal image is less bright, the latent period is longer. It might be thought that a source of light shining into the right eye would lower the apparent brightness of the pendulum by simultaneous contrast. This in its turn might lengthen the latent period and the apparent motion of the pendulum would be anticlockwise. This, however, is not so, and with an illumination of 15 ft.c. on the pendulum, a small electric torch shining into the right eye from a distance will produce a considerable clockwise rotation. Contrary to expectation, the extraneous source of light shining into the right eye has decreased and not increased its latent period. This result is probably due to nervous interaction between various parts of the retina since the illusion decreases progressively when the angle between the pendulum and the light source is increased, finally disappearing at about 30°. In addition, the illusion is not obtained when the image of the light source falls on the blindspot.

The illusion also appears when one eye looks through a sheet of glass in which is reflected the light from the open sky, and it does not matter whether the reflection of the sky covers the pendulum completely or merely covers the field of vision to one side of it. The latent period always appears to be shorter in the eye with the additional illumination. It might be thought that these experiments could be explained by saying that scattered light within the eye adds itself to the retinal brightness of the pendulum's image and so shortens the latent period of perception. That this is not the true view can be shown by the following experiment. When the electric torch is held close to one eye for a few seconds, that eye still has the shorter latent period even after the torch is removed. To the dazzled eye the pendulum appears much darker than to the normal eye, showing that the latent period can be varied independently of brightness and that there is no rigid connexion between them. The dazzled eye has apparently gained in quickness of perception but has lost in other ways. Frank Allen[2], working on the critical frequency of flicker, argued that because the fusion frequency of a test patch was higher when other parts of the retina were illuminated, that, therefore, the apparent brightness was higher. A given visual brightness is not followed by an unvariable latent period, and it is doubtful whether Allen was justified in assuming that, because the fusion frequency was raised, the apparent brightness was also higher.

It is rather surprising that the pendulum appears to swing almost straight after one eye has been dark adapted for five minutes or so, and we must conclude that the retinal interaction is largely confined to the mechanism of photopic vision.

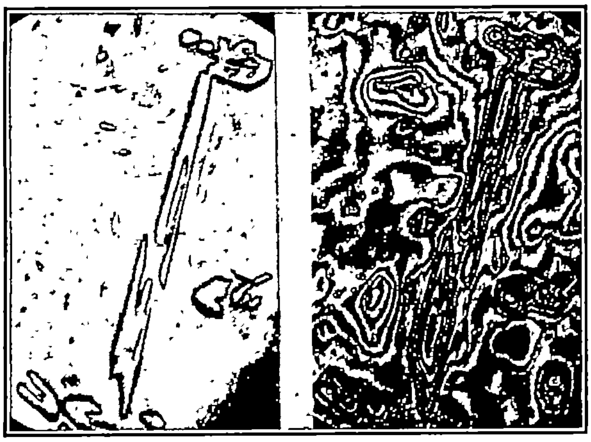
Metallography: a New Technique

The interference fringe technique for examining the topography of metal surfaces (previously used to study superficial irregularities in the coating of tin-plate[1]) has now been improved and its applications extended. The technique consists in observing or photographing the interference fringes that form between a partly silvered optical flat and the metal surface under examination. A detailed 'contour map' of the surface is thus obtained, the vertical spacing of the contours being one half the wave-length of the monochromatic (sodium) light used.



a *b*

Etched babbitt metal. (*a*) Vertical illumination; (*b*) interference fringes on the same field. (× 100).

A simple application of the technique is illustrated in the accompanying figure. The surface is that of a tin-base, tin-copper-antimony alloy (babbitt metal) which has been metallurgically polished and very lightly etched with 0·5 per cent nitric acid in ethyl alcohol. (*a*) is a photomicrograph taken with ordinary vertical illumination; (*b*) shows the fringe formation on the same field. It is apparent that the acicular structure of the copper-tin compound is at a level different from that of the ground-mass. The direction and extent of this difference can be easily determined.

In general, this technique can be applied to the study of any action which may give rise to characteristic differences of level in a surface. Irregularities caused by polishing a surface the constituent phases of which are not of equal hardness, or caused by differential attack of etching reagents due either to distinct phases or to varying crystal orientations of the same phase or to boundary effects, are all susceptible to study by the technique, and we hope to report more fully on some of these aspects in due course. The study of electro-deposited surfaces is also in hand.

The Kurumi (Japan) Meteorite

Mr. Yasuake Iba, a well-known Japanese amateur astronomer, wrote to the Harvard Observatory on October 7, 1934, that he had examined a meteoritic stone which fell near Kobe, Japan, on May 27, 1930. No reference to this fall appeared in two recent bibliographies of meteorites[1]; and for the completeness of the records it appears advisable to make known the information supplied by Mr. Iba.

At about noon on May 27, 1930, in Kurumi, a village near the town of Miki, north-west of Kobe, Mr. Jitsuzo Kuriyama and his wife were about to take tiffin when a rumbling sound attracted their attention. Suddenly something fell on the roof of their house. They rushed outside and saw steam rising from a near-by ditch and from it they dug out the main portion of the meteorite, 38 gm., 4 cm. × 3 cm. On the ground under their roof was found a fragment of 8 gm., 2 cm. × 1 cm., which was too hot to handle immediately. "The roaring sound in the sky which lasted for some time was so striking that the mechanics, busily engaged in the making of farm implements amidst a boisterous clamour of running motors, had to stop swinging their hammers to listen to it. . . . For the sound and the mass of the meteorite the damage was very slight, only one tile having been cracked."

The photograph (as reproduced herewith) and description sent by Mr. Iba show the stone to be a chondrite of "light sky-blue tint with yellowish granular particles (small patches) intermixed". (Only the two fragments were recovered, although others surely fell.) The name adopted in Japan for this fall is Kurumi Inseki (Kurumi meteorite), and Kurumi is apparently the name which should be generally adopted. The depository of the meteorite was not communicated, but can probably be given by Mr. Iba, whose address is Ohte, Kobe, Japan.

The Australian Aborigines

MAY I refer briefly to the important article on the Australian aborigines published in NATURE of December 18, 1937.

When Europeans took charge of the continent in 1788, there were, it is estimated, about 300,000 aborigines who had adapted themselves to the hard conditions of the Australian bush and had developed totemism and elaborate tribal customs. There are now none in Tasmania, about fifty in Victoria and a few in New South Wales. But in tropical Australia there are about 60,000, many of whom are afflicted with diseases, introduced by various races, and there are about 22,000 half-castes, European, Chinese, Japanese, etc., who are rapidly increasing.

The opinion of anthropologists seems to be that the pure aborigines will not survive unless they are placed on areas into which non-aborigines may not enter except on duty and where they may continue to live as they have always done. It is sometimes said by way of criticism that they have never cultivated an Australian plant or domesticated an Australian animal. This is, I believe, correct; but, in fairness, people must be reminded that the European has never succeeded himself in doing either of these things. Indeed, Governor Philip with his first party in Sydney in 1788 would in all probability have died of starvation where the aborigines thrived unless he had shipping resources at his disposal. Even then, he was hard put to it to save the settlement.

But biological historians remind me that the domesticated animals and cultivated plants, even in Europe, are prehistoric in origin though they have been developed out of recognition by skilled breeding. The Australian aborigine missed the opportunity, if it ever existed, of domestication and cultivation. As it is, the life of a European lost in the bush is usually very short. The feeling in Australia with regard to the preservation of the aborigine is growing steadily but the task is not easy. Medical care there must be, and I am personally of opinion that it will succeed only when either the aborigines or the half-castes are trained in medicine to some extent. Many of them can be useful on pastoral properties. The half-castes are often capable, and will, and must, be absorbed into the general population. It is in this direction that the missions can render great service and I believe in at least one instance are taking useful action.

Points from Foregoing Letters

DIALYSED extract of yeast, to which yeast adenylic acid is added, phosphorylates only glycogen and not glucose, according to H. Lehmann. As in the case of muscle extracts, this reaction, in which hexosemonophosphate is formed from glycogen and inorganic phosphate, reaches an equilibrium. The breakdown of glycogen to hexosemonophosphate is inhibited by glucose, a fact which may have a bearing on the regulation of carbohydrate metabolism in the living organism.

The magnesium content of hedgehog serum increases from an average of 3·20 mgm. per cent in the autumn, before the onset of hibernation, to an average of 5·43 mgm. per cent in January, during hibernation. This increase in the concentration of magnesium ions, unaccompanied by a corresponding increase in the concentration of calcium ions, produces, according to Dr. P. Suomalainen, an anæsthetic effect.

Prof. E. J. Conway states that the view that there is a constant rate of filtration of urine at the glomerulus and that variations in the urine volume excreted are almost entirely due to different volumes of water reabsorbed in the passage through the tubules, leads to a contradiction: on the one hand, the average 'clearance value' after administration of urea (so as to increase its concentration in the blood) remains the same, which shows that urea is reabsorbed in proportion to its 'lumen' concentration. On the other hand, increased rate of flow of urine through drinking more water also leaves the 'clearance value' unchanged, which indicates that the amount of urea reabsorbed is the same as before, hence unaffected by its lumen concentration.

Prof. A. M. Skellett points out that the number of meteors of the 8th magnitude or brighter, estimated on the basis of telescopic observations, entering the earth's atmosphere could account for the 'ionic clouds' detected in the *E* region of the upper atmosphere from their effect upon radio waves. The ionic clouds produced by meteors would have high ionic density and short duration.

The presence of 'stars' and 'clusters' of tracks, apparently due to protons, upon photographic plates impregnated with samarium and exposed to the action of cosmic rays at a high altitude in Kashmir (equivalent height 8,000 ft. above sea-level) is described by Prof. H. J. Taylor, D. Fraser and V. D. Dabholkar. The clusters appear to be associated with the presence of silver and bromine. Control plates at Bombay did not show the phenomenon to any appreciable extent.

R. Hultgren and L. Tarnopol find that substitution of silver for gold in gold-copper alloys decreases the temperature of transformation from the 'ordered' state—in which a gold atom is surrounded by eight copper and four gold atoms—to the 'disordered' state —in which each gold atom has on the average six gold and six copper neighbours. The experiments were carried out to determine the 'energy of ordering' due to interactions between neighbouring atoms, as distinct from that due to geometrical strain and the results, the authors state, agree with the predictions.

Dr. R. J. Lythgoe, using Pulfrich's rotating pendulum, calculates the increase in 'latent period' of vision produced by a given decrease in retinal illumination. Contrary to expectation, 'glaring' sources of light decrease the latent period both at the time and afterwards. The phenomenon is probably due to nervous interaction in the retina.

Describing a new metallographical technique, B. Chalmers and W. E. Hoare show that microscopic differences of level in a metal surface can be accurately measured by examining the interference fringes formed between the surface and a partly silvered optical flat.

Research Items

Effect of Physical Culture upon Women

THE results of an experiment conducted at the University of Minnesota on the effects of physical education for women have recently been issued ("Measurement of Outcomes of Physical Education for College Women". By Elizabeth Graybeal. University of Minnesota Press). Freshly entering women students were divided into two groups, one of which participated in a course of physical education, while the other control group did not. It was found that during a one-year period of experimentation, the experimental group made significantly—that is, statistically—greater gains than the control in attitudes towards health and physical education activities, in knowledge of health and physical education, and in general motor ability. In contrast to this result, the Health Organisation of the League of Nations (*Bull.* of the Health Organisation, 6, No. 4, p. 551) considers that women less than twenty-one years of age are not fitted for strenuous athletic effort, that the female organism fails to respond to intensive training, and that the majority of light athletics should be banned for women, flat racing being limited to 60–80 metres. Long runs, fencing, boxing and wrestling are considered unsuitable for women.

Mental Hygiene of Intellectual Work

DR. C. S. MYERS points out that, owing to the wide range of individual differences, it is impossible to lay down definite laws of mental health with regard to intellectual work ("The Mental Hygiene of Intellectual Work", *Occupational Psychology*, 12, No. 1). Some intellectual workers have done excellent work under the influence of drugs, whereas others have found them detrimental. Some work best when living a strictly ordered life, others when extremely irregular. Some work best at night, and some in the daytime. In learning and thinking, the emotional and conative factors are of fundamental importance: irritation, worry, anxiety, obsessional tendencies, and the consequences of other maladjustments and conflicts are obviously detrimental. Therefore normal affective conditions and unobstructed volition must be our ideal; thus it is not enough to 'train the intellect', since the whole personality in harmony with its social setting must be developed. Nor can we rule out the importance of interest and native talents. No intellectual work can be successfully performed without intellectual discipline, which, however, must not be understood as synonymous with mere routine. Interesting exercises could be planned and practised in order to improve intellectual work, with the result that disturbing impulses will be better controlled, thereby facilitating concentration and voluntary effort. Again, intellectual work has to be performed by means of the body and in a particular environment. There is a real need, therefore, for adequate food, exercise and sleep, as well as for the necessary material environmental conditions, such as lighting, heating, ventilation, and so forth.

Periodical Fluctuations in Game

PERIODICAL fluctuations in the number of individuals of various species is now well known and has been attributed to various causes. Mr. J. Baashuus-Jessen discusses this in regard to the smaller mammals of Norway in recent years in *Norges Svalbard-og Ishavs-undersökelser* No. 36 (Reprinted from *Norges Jeger-og Fiskerforbunds Tidsskrift*, Hefte 2 and 3, 1937). In 1934 there was a superabundance of small rodents, especially voles. This led to an increase in the number of foxes, stoats, buzzards, eagles and hawks and even of wolves. By 1935, the abundance of small rodents had stopped and there was a reduction in the number of hares and game birds which the beasts of prey had devoured, and these beasts in turn had become numerous. The year 1936 was marked by a great scarcity of game, but now it is expected that this will cause a reduction in numbers of foxes, eagles, hawks, etc. Mr. Jessen, while admitting the possibility of epidemics in reducing numbers of rodents, or their absence in allowing increase, thinks that climatic causes are more potent. A sudden thaw causes the drowning of lemmings. Drought or sudden frost may diminish nutriment and cause the prevalence of deficiency diseases. Migration, reduced fertility and diminished power of resistance to virus diseases may also result.

Snakes of Yucatan

THE peninsula of Yucatan juts into the Caribbean Sea from the mainland of Central America, and at its opposite ends exhibits extremes of meteorological, faunal and floral conditions. The composition of its fauna is therefore a matter of unusual interest. A collection of snakes, made by E. Wyllys Andrews in the States of Yucatan and Quintana Roo in 1937, was found by him to include forty-two species. Of these, the majority (24) belong to widespread species, six to sub-species which are off-shoots of forms found in the regions bordering the peninsula, and twelve are distinctive forms not connected by intergradation with the inhabitants of neighbouring areas (*Zoo. Ser. Field Mus. Nat. Hist.*, 20, No. 25, 355). The last of these groups seems to represent the relic of an earlier fauna which has now in part disappeared in the territory adjacent to Yucatan; while the second may represent adaptations of a later fauna to the peculiar ecological conditions of the northern part of the Peninsula. Some of the characteristic Yucatan species have been found to extend southward in the peninsula beyond the limits of the scrub forest.

Breeding Peculiarities of Hornbills

R. E. MOREAU directs attention to the curious breeding habits of African hornbills (Bucerotidæ), the females of which are enclosed in the nesting hole for periods which range from about six to ten weeks (*Proc. Zoo. Soc. London*, Ser. A, 33; 1937). This lengthy imprisonment includes a long period of brooding inactivity, the incubation of the eggs, and the partial development of the young to within three or four weeks of fledging. It covers also the moulting period of the female when she undergoes so wholesale a change that not only is the power of flight lost, but her body becomes almost naked. It is unlikely that non-breeding females should be subject to a process so drastic and dangerous, but evidence in their case is lacking. Problems of sanitation, intensified by the crowding of nestlings and parent in a restricted space, are overcome by forcible defecation at the entrance of the nest, by the ejection of other rubbish, such as egg shells and feathers, and by the 'casting' of indigestible remains. During the period of incarceration of the whole family, the male is solely responsible for food-getting, but in *Lophoceros* the female helps to feed the young after her emergence. In this genus the young, whenever the female leaves them, at once elaborate plaster, re-seal the entrance to the nest, and undertake the scavenging work formerly carried out by the mother bird.

Shells of Mauritius

The Revised Catalogue of the Testaceous Mollusca of Mauritius and its Dependencies by R. Viader (Mauritius Institute Bulletin, 1, Part 2, January 1937. Published by the Board of Directors of the Mauritius Institute and Public Museum) is an important and valuable addition to conchological literature. So much more is known of the Mollusca of Mauritius since the publication of von Marten's catalogue that the present up-to-date work was greatly needed, compiled as it is in accordance with modern classification. It is hoped that it will pave the way for the proposed thorough revision of the local fauna with bibliographical references, critical observations and ecological and other notes. The marine species and varieties listed in this catalogue number 2096 univalves and chitons and 279 bivalves, making a total of 2375, which exceeds by more than 1000 the number of shells reported by von Marten from the Mascarenes, the Seychelles and Madagascar. A number of species from recent gatherings are still awaiting description, and these will considerably enlarge the list.

Woodlice of Iceland

Only five species of woodlice have been recorded from Iceland; of these one—*Oniscus asellus*—is included, on very slender grounds, and two others, species of *Porcellio*, have been found only once. The distribution of the remaining species, *Trichoniscus pusillus* and *Porcellio scaber*, is confined to the south of the island, with the exception of three northern records ("Zoology of Iceland", 3, Pt. 28; 1938). Thydsen Meinertz suggests that the explanation of this localized distribution may be that Iceland is on the northern limit of the range of these woodlice, and that the milder insular climate of the southern part may afford suitable conditions while the continental climate of the northern area is too severe to permit of colonization. The suggestion is supported by the absence of woodlice in Greenland and by the solitary record from Norway north of Lofoten.

Monocotylous Seedlings of Some Dicotyledons

Most dicotyledons, as their name implies, possess two cotyledons, whereas monocotyledons have one; but certain dicotyledons show only one cotyledon (at any rate, at later stages in germination). Sir Arthur Hill has made some interesting observations on some of these monocotylous dicotyledons, especially on certain genera of Gesneriaceæ, and has recently published his findings, considered with observations on other species of plants (*Ann. Bot.*, New Series, 2, January 1938). Miss E. Sargant's theory (*Ann. Bot.*, 12; 1903), based on observations on the cyclamen, lesser celandine, etc., that the single cotyledon of monocotylous dicotyledons represents two fused cotyledons is shown to be untenable. Evidence is brought forward that the second cotyledon is either rudimentary and capable of development as in cyclamen, or wholly suppressed as in certain other genera. In certain species of *Peperomia*, the second cotyledon is an absorbent organ and never leaves the testa. In all genera of Gesneriaceæ studied, one of the two cotyledons was shown to cease growth at an early stage, and abort. The comparative morphology of the later stages in development of these genera of Gesneriaceæ is also discussed. The paper is illustrated by three plates of photographs and 23 text-figures.

Factors affecting Protein Content of Leaves

In the first of a series of investigations on nitrogen metabolism in plants, A. H. K. Petrie and J. G. Wood have studied the relation between the content of proteins, amino-acids and water in leaves (*Ann. Bot.*, New Series, 2, No. 5, January 1938). Experiments were performed on pure-line grasses, *Phalaris tuberosa* and *Lolium multiflorum*. The results obtained suggest that, in certain respects, the protein content of leaves varies directly with amino-acid and water content, and evidence was also obtained that the protein content increases with the *p*H of the expressed sap. It is suggested that the rate of formation of protein from amino-acids decreases with a reduction in water content, though it has not yet been established whether this decrease is due to decrease in protein synthesis or increase in protein hydrolysis, or both.

Ice in Finnish Waters

The distribution of sea-ice on the Baltic coasts of Finland is the subject of an exhaustive memoir by Dr. R. Jurva entitled "Über die Eisverhaltnisse des Baltischen Meeres an den Küsben Finlands" (No. 114 Merentutkinuslartoksen Julkaisu Havsforsknings Institutets, Helsinki, 1937). A feature of the study is the discussion of the ice distribution in various years so far as past records are available. Since all the Baltic coasts of Finland are to a greater or less extent fringed with ice in winter and so largely inaccessible to commerce, the records of the past are fairly numerous. The memoir is accompanied by an atlas of some fifty pages of maps and graphs of the ice distribution at all times of the winter. The maps give a clear view of the duration of frozen waters along the coasts.

Isocholesterol and Isomeric Ethers of Cholesterol

In 1937, E. S. Wallis, E. Fernholz and F. T. Gephardt (*J. Amer. Chem. Soc.*, 59, 137; 1937) by the action of anhydrous potassium acetate on cholesteryl *p*-toluene sulphonate in acetic anhydride obtained a new isomer of cholesterol which they called isocholesterol, and suggested that the reaction is accompanied by molecular rearrangement. A close relationship was suggested between this new alcohol and the isomeric ethers of cholesterol obtained by Stoll in 1932. It was further shown by E. G. Ford and E. S. Wallis (*ibid.*, 59, 1415; 1937) that the abnormal ethers of cholesterol recently referred to in the literature as "*cis*-cholesteryl ethers" are really ethers of isocholesterol. E. G. Ford, P. Chakravorty and E. S. Wallis (*ibid.*, 60, 413; 1938) have now substantiated the formula suggested for isocholesterol by a series of reactions involving oxidation and reduction. It appears that the hydroxyl group in this compound is in the six position of the sterol molecule and hence during its formation from cholesteryl *p*-toluenesulphonate a molecular rearrangement occurs.

Tetrahedral Angles in Butane Derivatives

THE tetrahedral form for the gas molecules of the tetrafluoride, tetrachloride and tetrabromide of carbon has been proved by the method of electron diffraction. Many other molecules, such as methylene chloride and chloroform, have been shown to be only slightly distorted from tetrahedral symmetry. Because of the electrostatic and steric repulsions of the methyl groups it is to be expected that the C-C-C angle in isobutane will be slightly greater than the tetrahedral angle 109° 28′. In the case of tertiary butyl chloride and bromide the increased steric repulsion between halogen and hydrogen atoms will be expected to decrease the C-C-C angle below that in isobutane and possibly below the tetrahedral angle. The electrostatic attraction of the negative halogen atom for the positive hydrogen atoms, on the other hand, would tend to spread the C-C-C angle. J. Y. Beach and D. P. Stevenson (*J. Amer. Chem. Soc.*, 60, 475; 1938) have measured these angles by the electron diffraction method. They find that the C-C-C angle is never distorted more than 4°, the values being 113° 30′ ± 2° for isobutane, 111° 30′ ± 2° for *t*-butyl chloride and 111° 30′ ± 2° for *t*-butyl bromide. These results are in agreement with calculations. The interatomic distances are calculated as C-C 1·54 ± 0·02, C-Cl 1·78 ± 0·03 and C-Br 1·79 ± 0·03, A. units.

Allotropy of Mercuric Oxide

THE two forms of mercuric oxide, red and yellow, have been regarded both as allotropic forms and as the same form in varying states of division. A. B. Garrett and A. E. Hirschler (*J. Amer. Chem. Soc.*, 60, 299; 1938) have determined the solubilities of the two forms in water, alkali and alkaline salt solutions. The solubility of the two forms can be represented by straight lines up to nearly 1 molal alkali and there is no perceptible decrease from the solubility in pure water. On the assumption that a hydroxide $Hg(OH)_2$ is formed, which is amphoteric, this result shows that the basic dissociation constant is very small, whereas the results for silver and copper oxides and cadmium hydroxide have shown substantially complete ionization. The value $K = [Hg^{\cdot\cdot}] \times [OH']^2/[Hg(OH)_2]$ is calculated as $1{\cdot}8 \times 10^{-22}$. The solubility curves in pure alkali establish the amphoteric nature of mercuric oxide by the constancy of the equilibrium constant $K = [H^{\cdot}] \times [HHgO'_2]/[H_2HgO_2] = 1{\cdot}4 \times 10^{-15}$. The difference in free energy between the red and yellow forms is calculated as only 31 g.cal./mol, but this is not regarded as establishing the identity of the two forms. Microscopic examination showed that the particle size was 1–10 μ for the yellow and 10–30 μ for the red. A sample of red oxide finely ground had a solubility 5 per cent greater than that of the yellow oxide although its colour was redder than the latter.

Photochemistry of the Atmosphere

VARIOUS reasons may be given for supposing that the earth's atmosphere originally contained no free oxygen. Its formation may possibly be due to photochemical decomposition of water vapour and carbon dioxide, which were present in large quantities. W. Groth and H. Suess have investigated this assumption (*Naturwiss.*, 26, 77; 1938). They point out that astrophysical observations indicate that solar radiation is very rich in exceedingly short wavelength ultra-violet. This does not reach the earth owing to absorption by oxygen and ozone, but the fact that lines due to excited nitrogen atoms occur in the spectrum of the night sky shows that radiation of wave-length about 600 A. must be present (Saha, *Proc. Roy. Soc.*, A, 160, 155; 1937). When water vapour is irradiated with ultra-violet radiation of wave-length 1295–1470 A., obtained from a Harteck xenon lamp, it forms hydroxyl and hydrogen ($H_2O + h\nu = OH + H$). Similarly, carbon dioxide gives carbon monoxide and oxygen ($CO_2 + h\nu = CO + O$). If a mixture of carbon dioxide and water vapour is irradiated, the two reactions go on simultaneously and the products combine to form glyoxal or formaldehyde ($H + CO = HCO$; $2HCO = H_2CO + CO$, or $HCO.HCO$). Their presence was shown by Schryver's reaction. The process is clearly similar to that occurring in carbon assimilation by plants. Not only could this process explain the formation of free oxygen in the atmosphere, but also the production of organic compounds, from which organic life could develop. The fact that a process of this kind is still taking place in the atmosphere is shown by the work of Dhar and Ram (NATURE, 132, 819; 1933), who detected as much as 1 mgm. per litre of formaldehyde in rain-water.

Degree of Accuracy in the Reduction of Occultations of Stars

MR. FRANK ROBBINS has recently dealt with the problem of the accuracy obtained in occultation reductions by three methods (*J. Brit. Astro. Assoc.*, 48, 4, February 1938). These are, the method advocated by the late Dr. R. T. A. Innes, modified and adapted for logarithmic computation by the Computing Section of the British Astronomical Association; the new method described in "The Prediction and Reduction of Occultations", which is based on Dr. L. J. Comrie's paper in *A.J.*, 46, 6, 1937; and a method described by Rev. Dr. M. Davidson in *J. Brit. Astro. Assoc.*, January 1938. Mr. Robbins points out that discrepancies amounting to 0″·3 or sometimes more occur in the results obtained by the first two methods. During the discussion at the February Meeting it was stated by Mr. D. H. Sadler, Superintendent of the Nautical Almanac Office, that each of these first two methods worked in units of 0″·1 in $\Delta\sigma$, and it was possible for the results to vary by one or two units, due to rounding off at different stages of the work. Dr. Davidson stated that he was not prepared to admit an error greater than 0″·04 by his method, and an error of 0″·1 would be utterly unjustifiable, especially if certain checks suggested by Mr. Robbins were utilized. In the February *Journal*, Dr. Davidson has a supplementary paper on the whole subject, in which he shows how considerably less work is entailed in the process of computation by his method, if functions of certain spherical co-ordinates are used instead of their direction cosines.

The Soviet Polar Enterprise

Some Preliminary Results

SOME preliminary results of the observations made on the drifting Soviet polar station are contained in articles supplied by the Soviet Union Year Book Press Service. Prof. V. Shuleikin, writing on currents and winds of the Arctic, says that the rate of drift of the ice is about three per cent of the velocity of the wind and that the drift deviated from the wind direction by so much as 45°. Further, he maintains that the pack-ice moves only by the action of the wind and that apart from the winds there were no surface currents observable in the Arctic Ocean. Thus there must obviously be a general prevalence of winds across the polar basin, for the observers are insistent that no sign of a circulatory movement of the floes within the basin was apparent. The East Greenland current is attributed to the persistence of north-west winds from the plateau of Greenland giving a southward movement, presumably in conjunction with the northward push of the ice due to the earth's rotation. It is said to be entirely a wind current.

Prof. N. Zubov points out that the conception of the Arctic as a region of continuous high pressure must be modified since cyclones penetrate to the region of the North Pole and bring relatively warm weather. If, however, the drift of the ice, which was principally to the south, is due solely to wind action it would appear that the wind must prevail from one direction and this may prove to be from the region of cold in north-eastern Siberia. There the radiation from a land surface results in lower winter temperatures than occur over the Arctic Ocean, where higher temperatures are maintained by the unfrozen water below the ice. The low pressure of the Greenland sea in conjunction with this high pressure over north-eastern Siberia would no doubt account for a pressure gradient leading to these transpolar winds. Previous observations on the winter drift of pack-ice north of Asia show some correlation with the air current from the Siberian high pressure area. In summer, northerly winds on the Asiatic coast, due to a change in pressure condition, fray out the edges of the pack towards the south. Comparable northerly winds seemed to have driven the Soviet floe southward on the other side of the Pole in summer.

Prof. L. Zenkevich, writing on the biological results, has little to say so far, except to record that fauna has been collected at depths of more than 1,000 metres. This is more than four hundred metres below the ridge between Greenland and Spitsbergen. Thus it would appear that the deep Arctic fauna is completely cut off from the faunas of the Atlantic and Pacific basins, and may well contain faunas of great interest. Lastly, Prof. O. Schmidt foresees further exploration of the inner Arctic basin by this novel form of transport on drifting ice, the only suitable means that has so far been adopted. The new magnetic observations will be a great help to future aviators, both in placing and removing such parties of floating observers. Aerial transport between Europe and the Far East will also be facilitated.

Veterinary Science in India

IN his presidential address before the Section of Veterinary Research of the Indian Science Congress Association at its recent jubilee meeting in Calcutta, Sir Arthur Olver discussed "The Development of Veterinary Work in India". Sir Arthur gave a detailed history of the early pioneers of veterinary science in India and the great efforts they made to lay down the foundation upon which the present structure had been built. So long ago as 1788, Joseph Earl published in Calcutta an English translation of a Sanskrit work on the diseases of horses entitled "Saluter and Farrier", and in 1799 a number of qualified veterinary surgeons, graduates of the London Veterinary College, were drafted to India for the organization of cattle and camel breeding and the establishment of studs for the breeding of cavalry horses. The most prominent among these was William Moorcroft, who was appointed in 1808 by the East India Company as superintendent of their Bengal stud at Pusa, in North Bihai; and it is recorded that by improved management he reduced losses by 90 per cent, and amongst other things introduced the cultivation of oats into India. Unfortunately, whilst on an expedition to Central Asia on behalf of his scheme to improve the breed of remounts for India he was murdered, but his writings were of exceeding value, not only on veterinary subjects but also in connexion with agriculture; and he is credited with having placed the Kashmer shawl industry on a sound footing, and to have described a breed of mountain sheep with wonderful wool and to have given an account of a new species of the genus *Equus* which was neither horse, ass, nor mule, and which he thought might have been the 'Onagar' of Pliny.

In 1821, in consequence of the terrible losses from disease amongst the animals, the East India Company insisted upon veterinary surgeons forming part of the staff of the various depots, and arranged a system by which Indians could be trained as assistant apothecaries to the troops of the Bengal Army. In 1823 a scheme was promulgated for an organized veterinary service, but the Veterinary Department of India remained without an official head or a single administrative officer for forty years; spasmodic efforts to fight the many tropical diseases from which the animals suffered being undertaken only in districts where there happened to be stationed veterinary officers of the British and Indian cavalry regiments. It was one of these, Dr. Griffith Evans, of the Army Veterinary Department, who, in 1881, for the first time, demonstrated a large flagellated organism, now known as *Trypanosoma evansi*—in the blood of horses and camels affected with surra, and this discovery was the pioneer work in the knowledge of protozoan diseases, and has since been of immense benefit to the human race as well as to livestock.

The years between 1860 and 1892 saw considerable advance in the organization of veterinary services in various provinces, and the formation not only of an army veterinary school but also several teaching schools and veterinary colleges. With these must ever be associated as pioneers the names of Hallen, Steel, Pease and Fred Smith; and in most provinces superior veterinary services were formed, officered by members of the Royal College of Veterinary Surgeons with subordinate services officered by graduates of the Indian Veterinary Colleges. The year 1891 marked one of the most important steps ever taken for the development of veterinary work in India, in the appointment of an Imperial bacteriologist; the sequel to which has been the establishment of the well-equipped and well-staffed Veterinary Research Laboratory at Muktesar. It was here that Dr. Lingard, who was the first Imperial bacteriologist, discovered the special affinity of arsenic for the parasite of surra; a discovery which has led to results of greatest importance to the human race. The more recent work of Dr. J. T. Edwards in the production of a goat virus of fixed and reduced virulence for the ox laid the foundation to what has proved a highly successful and economical method of controlling outbreaks of rinderpest amongst plains cattle, without the use of anti-rinderpest serum; the results being to confer a lasting immunity at a fractional cost of the serum methods which had been in vogue previously.

Sir Arthur Olver directed attention to the enormous field for scientific veterinary work which exists in India and deplores the paucity of trained scientific workers, and the heavy loss which could be avoided if more and more scientifically trained staff could be brought into action for combined veterinary and animal husbandry activities. He suggests that in addition to the five veterinary colleges which at present exist, at three of which the course is only three years, whilst at the other two the course is four, there should be added a Central India University Veterinary College. This would work in conjunction with the Veterinary Research Institutes of Izatnagar and Muktesar to train specially selected students who would be required to undergo a minimum of five and perhaps even six years of scientific veterinary research with special facilities for training in animal husbandry and a university matriculation to enable them to train up to modern standards and to carry out the higher diagnostic and research work which is so essentially necessary to control the epidemics of animals—especially in a tropical country like India, where the wealth and also the health of the people so largely depends on the health of its farm animals. As Sir Arthur said: "the field for such work is unlimited, and up to the present almost untouched."

The meeting of the Veterinary Section at the Indian Science Congress was well attended, and the papers on veterinary scientific subjects were of a very high order. One notable result ensued in that a proposal to add to future science congresses a Section of Comparative Medicine—in which medical men, veterinarians, physiologists, and those interested in animal husbandry could take equal part, was enthusiastically received and adopted.

The New Super-Novæ

A NUMBER of interesting notes on the discovery and the investigation of the two 'super-novæ', found within the course of a month, by F. Zwicky at the Mount Palomar Observatory, California, have been recently published in the *Astronomische Nachrichten*.

On an earlier occasion Zwicky (*Proc. Nat. Acad.*, 22, 459; 1936) had emphasized the great importance of extensive observation of these unique objects. Super-novæ radiate during several weeks as much energy as a whole galaxy of stars, and thus these data may furnish most valuable information on fundamental problems, such as the generation of energy in stars, the evolution of stars and stellar systems, the origin and the characteristics of cosmic rays travelling in space.

The latest discoveries, as well as earlier ones, for example, that in the nebula *NGC* 4157 in February 1937, are the result of a careful and regular search organized by Hubble, Baade and Zwicky, in the course of which the most important clusters of nebulæ were photographed as often as possible and tens of thousands of nebular images carefully searched for new stars (see *Publ. Astro. Soc., Pacific*, 49, 290; 1937).

Zwicky's recent super-novæ are of special interest because of their enormous absolute brightness, namely, −16, which makes them the most luminous stars known.

The first of these new stars, "Nova 144.1937 Canum Venaticorum", was found with the 18-in. Schmidt telescope in the faint nebulæ *I.C.* 4182 on August 31, when it had already reached the magnitude 8·5. It then faded rather rapidly; M. Beyer-Hamburg (*Astro. Nach.* No. 6307) recorded it on September 2 as 8·85 m., and by September 6 it had decreased to 9·8 m. In this period several spectra have been obtained by K. Walter and W. Strohmeier, of the Astrophysical Observatory at Potsdam (*Astro. Nach.*, No. 6308). The plates show on a rather strong continuous background some very wide emission bands, the whole spectrum having an appearance similar to that of a Wolf Rayet star of early *O*-type, characterized by bands at λ 4680 and λ 5411, He II, λ 5007, [O III], and the Balmer lines. Discussing spectra obtained at the Lick Observatory, D. M. Popper (*Publ. Astro. Soc. Pacific*, 49, 282; 1937) expresses the half-widths of the most distinct bands in km./sec. and finds a velocity of expansion of the star of about 4500 km./sec.

The other super-nova was discovered on September 10 in the east end of the nebula *NGC* 1003. Plates taken at the Hamburg-Bergedorf Observatory on September 6 and September 8 by A. Wachmann showed the star increasing from 13·6 m. to 13·3 m. (*Astro. Nach.*, No. 6310). On September 19, W. Strohmeier succeeded in obtaining an objective prism spectrum with the Potsdam 30-cm. reflector. This plate reveals strong emissions of He II at λ 5411 and of the nebular lines of [O III] at λ 5000, the width being about 200 A. The continuous spectrum resembles that of a *B*-type star. Neutral helium at λ 4471, 4388, 4144, 4026 appears in absorption. The Balmer lines are present as faint emissions, perhaps with violet absorption companions.

The photographic light curve of this super-nova, "145.1937 Persei", has recently been discussed by A. Beer and C. C. L. Gregory before the Royal Astronomical Society. This paper was based on a number of plates secured with the 24-in. Wilson reflector of the University of London Observatory at Mill Hill. The results show that the brightness of this nova was also fading rapidly. From 13·3 m. on September 20 it decreased to 13·8 m. on September 26, to 14·6 m. on October 3–4, and to 15·4 m. on October 9–10. Soon afterwards the star had become too faint for these observations. A high positive colour index is indicated, the visual brightness on October 12 being greater by 1·7 m. than the photographic value. No reports from the large American observatories are yet available, and nothing is known up to now about the doubtlessly very interesting spectroscopic results obtained there.

Development of Co-axial Cables for Television

ONE of the results of the modern developments in television technique has been the production on a commercial scale of cables capable of transmitting, with reasonable efficiency, alternating electric currents at frequencies up to one or two megacycles per second. These cables, which are of the concentric or co-axial type, are employed in the first place for conveying from the studio or outdoor scene to the television transmitter, the modulation frequency currents of the scene being televised. Such a cable is, for example, employed by the B.B.C. to connect the Alexandra Palace station to Broadcasting House and other important places in central London. But the scope of the application is now being extended to the use of the cables for the interconnexion of television transmitting stations separated by distances of the order of 100 miles. When the distance covered is of this order, the use of the cable is by no means limited to television, since the frequency band available provides a large number of ordinary telephone channels along the cable, thereby considerably augmenting the normal land-line trunk-connexion facilities. By a suitable arrangement of the relative frequencies, these telephone channels can be operated simultaneously with the transmission of the television signals, and the value of the cable is thus considerably enhanced. At the present time, a high-frequency co-axial cable is being installed by the Post Office between London and Birmingham, and the results of its operation will be awaited with interest.

Although Great Britain has been the pioneer country in operating a public television broadcasting service, the development and installation of these cables have been proceeding elsewhere, notably in Germany and the United States. The *Wireless World* of December 30 contains a note on the work of the German Post Office on a scheme for the linking-up of Berlin with other important towns. The cables in contemplation or actually undergoing installation will provide interconnexion between the television stations; the Post Office will further provide television-telephone facilities and in addition, arrangements have been made for sending as many as two hundred telephone conversations along the new cables in the frequency band not required by the television currents. For the purpose of transmitting television pictures on a basis of 441-line definition and interlaced frames at 25 per second, it will be necessary to instal amplifiers or repeaters at intervals of 10–12 miles along the cable. These repeater stations will be entirely unattended and will be supplied with power-frequency alternating current passed along the cable. Three types of cable made by different firms are being employed, and it is anticipated that the installations will be completed during the current year.

An interesting demonstration of the possibilities of these co-axial cables was provided last November by the transmission of a sound-picture film between New York and Philadelphia, a distance of ninety miles. This matter was briefly referred to in NATURE of December 4 (p. 962), and further details of the experiment have now been supplied by the Bell Telephone Laboratories. The cable in this case consists of two co-axial conductor units, each of which is formed of a flexible copper tube and a single concentric wire insulated at intervals with ebonite disks. Along the route are situated unattended installations of special amplifying equipment which receive their power supply over the two inner conductors. Each of the co-axial conductors with its associated one-way amplifiers is capable of transmitting simultaneously the currents from 240 telephone transmitters. Thus, using the two units of the cable for transmission in opposite directions, the system provides for 240 simultaneous conversations. In the present arrangement, the transmitters are formed into twenty groups of twelve, each transmitter being limited to a frequency band of four kilocycles per second. For the transmission of vision or picture signals, practically the entire frequency band of the cable—about one million cycles per second—is utilized.

In the demonstration to which reference was made above, a cinematograph film moving uniformly past a gate where it was scanned by a rotating disk system at a rate corresponding to 240 lines and 24 frames per second was used to provide a picture. The light passing through the film entered an electron multiplier, and the resulting current contained component frequencies between zero and about 800 kc./sec. For transmission along the cable, the frequency of this signal current was raised by modulation about 100 kc./sec. in order to avoid the portion of the range where transmission would be unsatisfactory and amplification difficult. In passing along the cable, the lowest frequencies fall behind the highest by a time amounting to some twenty microseconds. Delay equalizers were therefore developed to secure equal transmission times for all frequencies to within a quarter micro-second. At the receiving end a cathode ray tube was employed to produce a picture about eight inches square, and the demonstration provided satisfactory and clear reproduction of the scenes portrayed on the film at the sending end.

At the conclusion of the demonstration Dr. F. B. Jewett, president of the Bell Telephone Laboratories, stated that the experimental development was proceeding with the view of extending the operating frequency range of the cables and associated apparatus to at least two megacycles per second. This would provide a system capable of accommodating the maximum number of telephone channels which it is economical to handle on such a cable, or the widest band of frequencies which the best television scanning and reproducing apparatus may require.

Fuel Research in Great Britain

THE annual report of the Fuel Research Board[1] is always an interesting document because it covers so wide a range of topics that the reader can gain a fair conspectus of the problems engaging the attention of fuel technologists at the moment. The Coal Survey of Great Britain is probably, taking the long view, its most important task, and steady progress is recorded. With time, the scope of its activities increases as increased refinement in fuel processes makes greater demands on the supplies of raw fuel. The demand for cleaned, closely sized fuel grows at the expense of that for large lumps, and this creates many problems. The problem of breaking coal, removing dust and fine coal, clarifying wash water grow in importance. In Yorkshire, efforts are being made to reduce the number of standard sizes, which are bewildering in their number and names. The dust-proofing of coal by spraying it with suitable oil or other liquid to prevent the raising of dust when disturbed is another problem receiving study.

The investigation of the production of oil from coal continues. The staff at Greenwich has studied the process of carbonization at low temperatures from the outset and evolved a design of vertical retort for the purpose. It is now reported that a setting of these retorts has been in operation at the South Yorkshire Chemical Works Ltd., near Rotherham, during the period under review and has given entire satisfaction.

A more comprehensive account of the Fuel Research Board's work on domestic fuels is found in Technical Paper No. 46, describing the results of Mr. J. S. Hales' observations on the use of coke in open fires[2]. Although it covers some ground previously traversed by others, only good can follow repeated assertion of experimentally ascertained facts so imperfectly known or understood. Although fire has been used by man through the ages, until recently no quantitative answers could be given to some of the simplest questions. This is exemplified in Mr. Hales' report, for he deemed it necessary to show by experiment that the rate of combustion of an open fire is not changed by opening or closing a canopy, if fitted.

Great ignorance prevails as to the relative merits of coals and cokes so that the view—encouraged by some coal merchants—is common that coke is a debased fuel fit only for the indigent. In this connexion, the general conclusion of this report is important, namely, that " 'combustible' coke may be superior to normal household coal from the point of view of freedom from smoke, easy ignition and rate of initial combustion, but that the control of the rate of radiation of heat can be more easily achieved with coal". It ought to be pointed out that a measure of control is possible, but the consumer needs educating in the technique of using carbonized fuels.

The basis of test used is the measurement of radiation in one direction emitted by a fixed *volume* of fuel in a single charge. This method gives useful information capable of interpretation by a discerning reader. Fuel, however, is bought by *weight*, and the undiscerning reader may get a wrong idea of the comparative cost of the unit of radiated heat, from the statement that the maximum radiation from a normal household coal may exceed by 30 per cent that from a coke. This apparently relates to equal volumes of fuel and the fact is obscured that the rate of consumption of the coal probably exceeds that of coke by 50 per cent.

The third report of the Oil from Coal Committee issued by the Scottish Development Council merits attention not merely for its contents, but also as an example of local initiative[3]. Areas hit by depression may have been richly endowed with natural resources. Those who have exploited these resources have often been content to take out great wealth without 'ploughing in' sufficient to develop subsidiary industries. Thus a decline in the main industry leaves the area economically stranded. The efforts of the Scottish Development Council set a good example of the local self-help by scientific study of the possibility of grafting new industry upon old stock. The report deals with experiments on the low temperature carbonization of Scottish coal, but the conclusions are not too hopeful as to the economic aspects.

The Duke of Montrose criticizes the manner in which the Committee has approached the problem of marketing, and there is force in his criticism. No one familiar with the matter will expect the use of raw coal to be easily displaced and the consumer must be educated to understand the conclusions of the Technical Paper No. 46 (v.s.), namely, that cokes have advantages as well as disadvantages. The technique of using them must be taught and the organization of sales and distribution will require effort, otherwise the best laid scheme may fail. Thus in one town municipal houses were fitted with grates suitable for burning coke, but no organization was provided for the regular distribution of suitable fuel in small quantities; the tenants consequently burn coal delivered at the door. H. J. H.

Science News a Century Ago

Progress of Statistical Studies

THE anniversary meeting of the Statistical Society was held on March 15, 1838, the Earl Fitzwilliam being elected president. In the report of the Council read at the meeting it was said: "The direct and incidental use which, at present, is made of statistical documents in scientific and philosophical writings on the most important moral and political questions, and the now frequent insertion of statistical notices in the publications of the day, may be adduced as indicating the prevalence of a sense of the indispensable necessity of continually adverting to the tabulated numerical results of systematic inquiries. It is, indeed, truly said, that the spirit of the present age has an evident tendency to confront the figures of speech with the figures of arithmetic, since it is impossible not to observe a growing distrust of mere hypothetical theory and *à priori* assumption. But a more decisive proof of the just estimate which is formed of the value, and of the deep interest which is felt for the result of statistical researches is presented in the continual formation of new societies." The report then went on to refer to statistical organizations in Liverpool, Ulster, New York, Turin, Calcutta, Manchester, Bristol and York.

Nathaniel Bowditch (1773-1838)

ON March 16, 1838, Nathaniel Bowditch, the American mathematician, died at Boston at the age of sixty-four years. He was born in Salem, Mass., on May 26, 1773, of poor parents. At the age of twelve years he was placed in a ship chandler's shop, but by his own exertions became a good mathematician and learnt Latin in order to read Newton's "Principia" in the original. Leaving the shop when twenty-one years of age, he went to sea as a clerk and rose to be a master. In 1800 he published his "Practical Navigator", and quitting the sea in 1803 became president of an insurance company in Salem. Twenty years later he was made actuary to the Hospital Life Insurance Company, Boston, then the largest institution of its kind in the United States. He was offered chairs of mathematics at Harvard, in the University of Virginia and in the Military Academy at West Point, but declined them. For several years he was president of the American Academy of Arts and Sciences and contributed many papers to its transactions. The great work of his life was the translation of, and his commentary on, Laplace's "Mécanique Céleste" in four volumes of over a thousand pages each. He commenced this work in 1815 and was correcting the proofs of the last pages of the fourth volume when he died. The work met with a flattering reception both in America and Europe. He was elected a member of many societies, including the Royal Society, and the Royal Society of Edinburgh, and for twelve years was a fellow of Harvard College.

Parrot's Observations at North Cape

IN the *Athenæum* of March 17, 1838, it is stated that Prof. Parrot, well known for his travels to the Caspian Sea and Caucasus and more recently for his ascent of Mount Ararat, made a journey in the course of last summer to North Cape, for the purpose of making astronomical and magnetical observations, and of noting the oscillations of the pendulum at the most northern point of the European continent. Leaving Dorpat on July 10 he reached Tornea on July 23, proceeded 380 miles up the Rivers Tornea and Muonio and reached the source of the latter close to the borders of Sweden, Norway and Russia. Leaving his boat, his instruments were carried by eight Finlanders to the inlet Lyngen Fiord, where he embarked in a small boat for a journey of 200 miles to North Cape, which he doubled on August 25. His observations were made under favourable circumstances. He returned to Dorpat in December with, it is presumed, a rich harvest of philosophical materials.

Anthracite Coal for Iron Smelting

THE *Mechanics' Magazine* of March 17, 1838, quoting from the *Cambrian*, said: "On Friday the 23rd ult., a public dinner was given at Swansea to Mr. Crane, the inventor and patentee of the application of anthracite coal to the smelting of iron ores. Mr. Crane was invited by public requisition from upwards of one hundred mineral proprietors and others, interested in the successful results of his valuable discovery. . . . The practical application of Mr. Crane's discovery has now been fully tested for upwards of twelve months at the Yniscedwin Iron Works. . . . His success will, we trust, stimulate others to the application of this valuable fuel to other branches of trade. Already we hear that the experiments are now in progress, and we have every reason to believe that ere long the economical application of this coal for the generation of steam in marine engines will be proved beyond a doubt."

Forthcoming Events

[*Meeting marked with an asterisk is open to the public.*]

Monday, March 14

Royal Geographical Society, at 5.—Discussion on the Air Almanac to be opened by Dr. H. Spencer Jones.

Tuesday, March 15

University of Cambridge (Cavendish Laboratory), at 3.—Prof. W. Pauli: "Contributions to the Theory of Field Quantization" (succeeding lectures on March 16 and 18).

University College, London, at 5.—Prof. A. P. H. A. de Kleijn: "Some Remarks on Vestibular Physiology".*

Wednesday, March 16

Royal Meteorological Society, at 7.30.—F. Entwistle: "Atlantic Flight and its Bearing on Meteorology" (Symons Memorial Lecture).

Society for the Study of Alchemy and Early Chemistry, at 8.—Prof. R. Campbell Thompson: "Assyrian Chemistry of the Seventh Century B.C."

Thursday, March 17

Chemical Society and Physical Society (joint meeting at Burlington House, Piccadilly, W.1), at 8.—Discussion on "Electron Diffraction and Surface Structure", to be opened by Prof. G. J. Finch.

Friday, March 18

Royal Institution, at 9.—Sir William Bragg, P.R.S.: "Ice".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Technical Officer (male) in the Meteorological Office—The Secretary (S.2.A.), Air Ministry, Adastral House, Kingsway, London, W.C.2 (March 12).

Junior Assistant Bacteriologist in the Department of Pathology, Postgraduate Medical School, Ducane Road, London, W.12—The Dean (March 14).

Lecturer in Psychology in the Brighton Municipal Training College for Women—The Education Officer, 54 Old Steine, Brighton (March 18).

Assistant (grade II—engineering or physics) at the Air Ministry Headquarters—The Secretary, Air Ministry (S.2.D.), Room 8.205, Kingsway, London, W.C.2 (March 18).

Teacher of Chemistry in the Northern Polytechnic, Holloway, N.7—The Clerk (March 23).

Assistant (lady) to the Director of Research, Wool Industries Research Association, Torridon, Leeds—The Secretary (March 24).

Assistant Chemist in the London Shellac Research Bureau—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (March 25).

Assistant Administrative Officer in the Research Department, Woolwich, S.E 18—The Chief Superintendent (March 25)

Lecturer in Electrical and General Engineering in the Faraday House Engineering College, Southampton Row, W.C.1—The Principal (March 26).

Three University Demonstrators in Anatomy in the University of Cambridge—Dr. F. J. W. Roughton, Department of Physiology, Cambridge (March 31).

Investigator (welding) in the British Non-Ferrous Metals Research Association, Regnart Buildings, Euston Street, London, N.W.1—The Secretary (March 31).

Secretary of the London School of Economics, Houghton Street, Aldwych, W.C.2—The Director (March 31).

Research Assistant (computational work) in the Mathematics Department, Imperial College of Science and Technology, South Kensington, S.W.7—The Secretary (April 21).

Lecturer in Physiology in the Queen's University, Belfast—The Secretary.

Professor of Engineering in the Queen's University, Belfast—The Secretary.

Assistant Civil Engineers in H.M. Office of Works, Storey's Gate, S.W.1—The Chief Architect, Room 65 A/3.

Assistant (grade II—engineering) at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (March 18—quote Ref. No. 361B).

An Educated Democracy

AMONG the social services which have undergone remarkable developments in Great Britain during the present century is that of education, and particularly of secondary education since the passing of the Education Act of 1902. The actual and potential changes in the structure of society brought about by these expansions of educational opportunity are far-reaching, yet it may be doubted whether their significance is generally appreciated. This is the view of Mr. G. A. N. Lowndes, who in a recent work with an arresting title[*] says: "Nothing is more exasperating to those to whom social reform is religion in action than the readiness with which the English neglect, forget or minimize their achievements." Mr. Lowndes recalls and appraises those achievements in the field of public education, elementary, secondary and technical, in the past forty years, thanks to which Great Britain, it is claimed, is becoming "an educated democracy". Some of the most telling in the series of contrasts through which the magnitude of these achievements is presented illustrate the progress of secondary education—progress which has been rightly characterized as 'revolutionary' by statesmen and historians.

The secondary school population has quadrupled and now includes 350,000 former pupils of public elementary schools. In 1934 the proportion of elementary school pupils, aged 10–11, passing into secondary schools was 119 per thousand, whilst in 1895 the corresponding proportion (elementary school leavers passing on to endowed grammar schools) was probably not more than 3–6 per thousand. Forty years ago the number of pupils holding county and county borough scholarships at schools of secondary type was 2,414, as compared with the 224,981 total, and 23,188 partial, exemptions from payment of fees in grant-aided secondary schools in 1934.

These figures indicate an appreciable advance towards that elusive goal—equal educational opportunity for equal abilities. A similar advance is discernible when one turns to statistics of the output from the grant-aided secondary schools to the universities. Of the 4,192 students who passed from those schools to universities in 1934 (London 1,040, Wales 613, Cambridge 463, Oxford 382, other universities 1,694), 1,983 of the men and 831 of the women had begun their education in elementary schools; 2,209 had paid no fees. Comparable statistics of forty years ago are not given, but Mr. Lowndes recalls a reply given by a witness examined by the Cross Enquiry Commission in 1888 to a question as to the prospects of a public elementary school pupil ever reaching a university: "It would be next to expecting a boy out of the London Board Schools to take wings . . .", and adds "He was right."

The output from the grant-aided secondary schools to the universities has been a subject of comment in the Board of Education's reports since 1924, when in the course of a comprehensive review of secondary education attention was directed to the rapid increase of this output between 1909 and 1921 from 1,056 to 2,888, chiefly ex-public elementary school pupils. The following year the Board remarked: "It is commonly assumed that a secondary school provides an avenue to the university, at any rate for able pupils. Fifteen years ago this assumption was not generally warranted." In 1909–10 about 400 out of 950 schools on the grant list sent one or more pupils to the university. By 1924 there were very few that did not at least occasionally send one. In 1932 the output to the universities had increased to 4,560 and since then the numbers have declined, the total in 1935–36 being 3,578.

---

[*] P. 236 of "The Silent Social Revolution: an Account of the Expansion of Public Education in England and Wales, 1895–1935". By G. A. N. Lowndes. Pp. xii+274+8 plates. (London: Oxford University Press, 1937.) 6s. net.

The position in regard to assisted students in the universities was reviewed by the University Grants Committee in the last quinquennial report (for 1929–30 to 1934–35). The Committee emphasizes the extent to which the approach to the universities is made possible by scholarships, maintenance allowances, or eleemosynary grants. At least £1,350,000 is spent in this way annually by Government departments, local education authorities, universities, Oxford and Cambridge colleges and the trustees of public endowments in Great Britain. The Committee adds that fifty per cent of the students in the provincial universities began their education in public elementary schools. In further illustration of the same point may be cited, from the Board of Education's report for 1935–36, the fact that out of 719 open scholarships at Oxford and Cambridge 374 were won by pupils at the grant-aided secondary schools, of whom nearly three fourths had paid no fees and two thirds had been previously educated in public elementary schools.

The contribution of the grant-aided secondary schools to the universities is really greater than that represented by the Board's statistics already mentioned, because these exclude the considerable number of students who enter universities after an interval instead of proceeding immediately from school. The number so excluded was estimated by the Board in 1925 to have been about ten per cent; according to Mr. Lowndes, twenty per cent is nearer the mark. Assuming the intake of the universities from this source to be between four and five thousand, how does this compare with the intake from other sources? The total of admissions into the universities of England and Wales is about twelve thousand, of whom about ten per cent are from outside the British Isles. Whence come the remainder, from six to seven thousand, who do not come from the grant-earning secondary schools? With very few exceptions, from the other secondary schools. The grant-aided schools account, according to an estimate in the University Grants Committee's report, for five sixths of the whole secondary school population. The estimate is perhaps a high one, but it seems plain that more than a moiety of the influx of students is from a comparatively small catchment area.

This state of affairs is, of course, associated with that dual system of which Lord Baldwin declared in 1929 "the interests of social unity demand the removal of this source of class prejudice", but which seems immune to the equalitarian influences of the "silent social revolution". Its most obnoxious feature is that, as the authors of "In Defence of Democracy" (Methuen, 1935) put it, it operates to make the consciousness of social difference all pervasive in the working of men's minds in all social and political questions. The success of Rendcombe College goes to show, however, according to Mr. J. H. Nicholson ("Education for Modern Needs": Ivor Nicholson and Watson, 1936) that this feature can be eliminated from the "public schools". Certainly any tendency to divide the community into mutually unintelligible groups is specially to be deplored at a time when a maximum of social unity is needed for meeting the challenge involved in the rise of the powerful and energetic totalitarian régimes.

To that challenge Mr. Lowndes's book makes no reference; nor have the achievements he tells of contributed conspicuously towards generating that active vigorous citizenship in harmony with democratic principles which is indispensable for their maintenance. The sectional loyalties fostered in so many of our schools are not enough, and wider views will have to be taken if education is to provide a firm basis for constructive democracy.

During the past four years, much valuable work in this direction has been done by the Association for Education in Citizenship, of which Lord Baldwin has recently accepted the presidency. It seeks "the best methods of educating citizens who are likely to maintain and strengthen our democratic system". Much promising exploratory work has been done in various schools (see the Association's "Experiments in Practical Training for Citizenship"), but it has to be recognized that any training for citizenship before the age of fourteen or fifteen years, when the great majority of citizens of the future leave school, can be but very elementary. The British genius for self-government was evolved in the hard and efficient school of learning by doing in days when every village householder had to do his bit of community service, and training in citizenship for the million must await the acceptance by the nation once again of the burden of national service for all.

Frazer on Totemism

Totemica:
a Supplement to "Totemism and Exogamy". By Sir James George Frazer. Pp. xii+518. (London: Macmillan and Co., Ltd., 1937.) 25s. net.

HALF a century ago, in 1887, there appeared in Edinburgh a small booklet entitled "Totemism". It was destined to exercise an influence on the science of man second only to that of another masterpiece by the same author—I mean of course Frazer's "Golden Bough". Both works produced an immediate impression at home among scholars and abroad among workers in the field. Both have since reappeared in a much fuller form; the first as "Totemism and Exogamy" (in four volumes, 1910); the second as a series of twelve volumes jointly named "The Golden Bough" (1911–15).

Each of the two great works has now received a valuable epilogue: "Aftermath", a supplement to "The Golden Bough", published last year; and now "Totemica", giving the finishing touch to Frazer's work on totemism. To those of us who owe the main inspiration of our life-work to Frazer these recent events are both welcome and significant. The additional volumes bear witness not only to the vigour and creative power of the author but also to the value and vitality of the British school of anthropology.

Frazer, more than anyone else, has given the science of man wide currency among cultured people all over the world. It is largely due to the literary charm of his style and the profoundness of his insight that anthropological books are now extensively read, appreciated, and enjoyed. He also, above all others, has brought anthropology into line with classical scholarship. Nor is it an accident that the first systematic and planned scientific expedition was undertaken from Cambridge, Frazer's spiritual home and personal abode. The work of Spencer and Gillen in Central Australia, the researches of Roscoe among the Baganda, the African classics of Smith and Dale, of Rattray, and of Junod, throughout bear witness to Frazer's genius and vision.

The direct imprint of Frazer's ideas on anthropological theory is not less remarkable. Take the range of its subject-matter: magic and kinship, social organization and the clan system, political power and problems of early science, of ritual and religion: in all these Frazer has given at least the initiative and in most cases the fullest and most adequate treatment of each subject. When the great Frenchman, Durkheim, was shaping his theory of primitive religion, he had in "The Golden Bough" an encyclopædia of fact upon which to draw, and a compendium of theoretical points of view to inspire him. When Freud made his attempt to apply psycho-analysis to the 'cave man' and his murderous and incestuous offspring, he turned to Frazer's "Totemism and Exogamy" and to "The Golden Bough". Most modern schools of anthropology, whether 'functionalism' or 'structuralism', the search for 'patterns of culture' or hunt for 'tribal geniuses', largely depend for their inspiration on Frazer.

The present book is a review of evidence on totemism which has accumulated since 1910. It is arranged geographically, pride of place being naturally given to Australia: ". . . for it is to Australia, with its varied and very primitive forms of Totemism, that we must ultimately look, if we are ever to find a clue to the problem of the origin and meaning of the institution" (from the preface). From that continent some new and important facts have been brought to light in field-work organized from Sydney by Prof. A. R. Radcliffe-Brown and his successor Dr. A. P. Elkin. Some of the discoveries, such as those by R. Piddington and P. M. Kaberry, W. E. H. Stanner and U. McConnel shed a new light on our theoretical conception of totemism.

Readers of Frazer, that is, all anthropologists, will note with interest that the new evidence establishes the widespread occurrence of two facts: the ignorance of physical paternity and the magical ceremonies for increasing totemic species. It is on these two ethnographic facts that Frazer founded his hypotheses of the origins of totemism.

Equally rich and interesting is the evidence from Oceania. It has been known since the times of Codrington that developed forms as well as the rudiments of totemism are to be found in Melanesia. Its occurrence among the Polynesians, foreshadowed by Rivers, has since been established through the recent researches of Drs. R. W. Firth and H. I. Hogbin. The data from Africa and India which Frazer is able to register in the present book, important as they are, do not add anything revolutionary to our knowledge. America, the continent in which totemism was discovered, has yielded only twelve pages.

Frazer himself keeps aloof in this book from controversy; nor does he work out his earlier theories any further. It is tempting, therefore, to inquire how far these have been strengthened or modified by recent discoveries and developments in anthropological doctrine. In his first theory, dating back to the original book of 1887, Frazer finds the origins of totemism in the widespread belief in the external soul, a belief in which primitive man associates his welfare and destiny with some symbolic object. Organized on a communal scale, that is, associating a whole clan with an animal or plant species, this belief becomes in substance totemism.

Frazer himself has discarded this view as a theory of the origins of totemism. We cannot, however, dismiss it as a contribution towards the understanding of the primitive tendency to symbolize, nor yet of the constitution of primitive society. An external symbol seems to be indispensable in the integration of primitive, and for that matter even of civilized, groups. Durkheim, developing Frazer's theories more fully, has rightly insisted on the functional value of the Australian *churinga* and of our modern flag, of the medieval scutcheon, and the crown and sceptre of contemporary monarchs. The appreciation of social symbolism, of the concept of the external soul in its wider setting, reveals to us some of the workings of the primitive, that is, essentially human mind, and of group integration at all levels of development. For the progress of civilization in a way consists in the imprint of things spiritual being given to matter, while shaped matter fashions spiritual processes in turn. The very essence of symbolism in thought, in speech and writing, in liturgy and in art is, after all, nothing else but the concept of 'external soul' developed and refined beyond recognition and yet without any breach of continuity. Thus Frazer's first hypothesis can be regarded as the starting-point of some of the most important developments in the study of culture.

The second theory, formulated by Frazer after the sensational discoveries of Spencer and Gillen in Australia, links up totemism directly with magic. The Arunta and allied tribes perform magical ceremonies of totemic increase in which every clan acts as a co-operative unit in a vast enterprise of multiplying edible and otherwise useful animals and plants. The means to this practical end appear to us completely fictitious. This, however, does not detract from their social and even educational value. They bring home to the participants the importance of co-operation, the necessity of obeying rules and following tribal tradition—an aspect of ceremonial life brought out by Prof. Radcliffe-Brown in the second part of his "Andaman Islanders".

The role of magic as an all-important organizing and integrating force can be seen even more clearly at a level higher than that of the Australian and Andaman islander. In the Trobriand Islands the garden magician, in virtue of his mystical power over Nature, becomes the leader and organizer of the enterprise: he acts as the agricultural expert and supervisor of work (*cf.* "Coral Gardens" by the reviewer). So also the man who magically controls wind and weather, the dangers of the open seas, and the vicissitudes of the commercial moods of his trading partners, acts as captain of the canoe and master of an overseas expedition ("Argonauts of the Western Pacific"). As regards Polynesia, the connexion between magic and practical activities has been well documented by Dr. R. W. Firth in his "Primitive Economics of the New Zealand Maori" (1929).

In his third and final theory of totemic origins Frazer reveals the significance of the primitive ignorance of physiological paternity. Here once more the Central Australians provide the cue. They believe that conception is due to the entry into a woman's womb of a totemic spirit-child. These are believed to reside in sacred spots, primarily deposits of bull-roarers (*churinga*), where mythical ancestors, half-human, half-totemic, had left their souls and their magical implements. This belief, argues Frazer, is sufficient to explain the reason why primitive man regarded himself as mystically bound up with an animal, plant, or inanimate object. It accounts also for the formation of clan bonds, and it explains why, through his totemic kinship with natural phenomena, primitive man claimed magical control over natural processes and objects.

At the time when Frazer was setting forth his theory, he was really generalizing boldly—some might even say, too boldly—from evidence confined to one insignificant tribelet in the deserts of Central Australia. Yet here once more Frazer's genius had anticipated the course of future discoveries. Animistic beliefs about conception have since been discovered in one tribe of Australia after another until their distribution map almost covers the continent. They have been signalled by Rivers from Melanesia, by the present reviewer from eastern New Guinea, and by Dr. Hogbin from Polynesia.

It is interesting to note that simultaneously with Frazer's "Totemica" there appears a monograph dealing with totemic paternity in aboriginal Australia. It is really a monument to Frazer's insight and vision, and to the value of his theories of totemism (M. F. Ashley-Montagu, "Coming into Being among the Australian Aborigines" 1937). Dr. Ashley-Montagu concludes that, with very few and insignificant exceptions, "the orthodox doctrine of each tribe" in Australia is "that children are the result of the immigration into a woman of a spirit child which is of an origin going back into the far distant mythological past. . . . Thus it is that by means of this belief in the immigration of spirit children into women the proper totemic and moiety membership of the child is secured". (*Op. cit.* p. 199.)

Taking any one of the three hypotheses in isolation, it might be contended that none of them alone is sufficient to account for the birth and nature of totemism. Taken in conjunction, they give a full and adequate explanation of the phenomenon. They all centre round the conception, almost the definition, of totemism which runs through Frazer's theoretical treatment and gives the perspective to his magnificent edifice of fact: totemism expresses ritually and mythologically man's selective interest in a number of animal or plant species; it discloses the primitive's profound conviction that he is in body and mind akin to the relevant factors of his environment. These he is able to control magically in virtue of the kinship; and towards them he has to observe a religious attitude of reverence and consideration.

In any theory of totemism, we have first and foremost to account for the linking of man with environmental forces and principles. In his third theory, Frazer makes the important suggestion that the primitive ignorance of reproductive physiology combined with beliefs of spirit-child incarnation is the natural basis of totemic kinship between man and Nature. This bond was to primitive man not merely an intellectual affirmation and a sentimental attitude; it became above all a means of action. Since his interest in his surroundings was pragmatic, that is, nutritive and utilitarian, and his earliest means of control magical, the main function of totemic belief consisted in the ritual of magical increase directed upon useful or practically important factors of the environment. Thus we are led inevitably to Frazer's second hypothesis, in placing the first within the context of primitive thought, feeling, and action.

Such terms and concepts, however, as 'principles of fertility', 'useful environmental factors' go beyond primitive man's intellectual horizon. He has to use concrete and tangible symbols, both ritually and psychologically. The principle of ritual symbolism, that is, the belief in the external soul, on which Frazer lays emphasis in his first theory, is the indispensable corollary to our understanding of the magical function of totemism and of its conceptual origins. The Australian *churinga*, for example, is the prototype of the external soul. In native belief it is also the main reservoir of spirit-children. In the increase ceremonies it becomes the main instrument of magical efficacy. This small object embodies as it were and epitomizes Frazer's hypotheses of totemic origin; and, let us remember, to the Central Australian the *churinga* is the most sacred and important object in the whole universe. It represents to him tradition, magical force, and the social unity of the clan, condensed but all-powerful. It stands for a long line of ancestors; it gives man the means of securing wealth and welfare; it is the source of human fertility. In 'singing' to his *churinga*, in his mythologies and ritual actions, the Central Australian pragmatically bears witness to the intuition and insight of the great historian of totemism.

Frazer's theories explain not only the origins of totemism but also its functions. From the survival point of view, it is vital that man's interest in the practically indispensable species should never abate, that his belief in his capacity to control them should give him strength and endurance in his pursuits and stimulate his observation and knowledge of the habits and nature of animals and plants. Totemism, in the light of Frazer's theory, appears thus as a blessing bestowed by religion on primitive man's efforts in dealing with his useful surroundings, upon his 'struggle for existence'. At the same time it develops his reverence for animals and plants on which he depends, to which he feels in a way grateful, and yet the destruction of which is a necessity to him.

Frazer's interpretation of totemism gives us still the best insight into the earliest phases of religion, of man's pious attitude of dependence, of his early seeking for permanent tangible values instinct with spiritual and moral substance. Within the framework of Frazer's interpretation we see how in totemism the beginnings of ethical attitudes are developed through the magical co-operation of clan members, and of the clans for the welfare of the whole community. Frazer has also shown that totemism, in its insistence on material symbolism, contains perhaps the earliest rudiments of sacred metaphor, that is, of abstraction, with all its possibilities of development into ritual, on one hand, and science on the other.

Frazer's contribution has been as essential to the progress in empirical field-work as to our theoretical understanding of primitive man. More than that, in his great works, "The Golden Bough", "Totemism and Exogamy", "The Fear of the Dead", "The Belief in Immortality" and "Folklore in the Old Testament", Frazer has given us in outline a lasting philosophy of culture capable of indefinite development.

The extraordinary sympathy and insight with which the leader of the British school has treated primitive ways of thought and action, his fundamental humanism, his scientific acumen and artistic intuition have allowed him to reveal most of the problems with which modern anthropology is concerned. Frazer's vision has also led him to foresee the main currents of empirical discovery and to lay down the foundations of the comparative science of human cultures.

B. MALINOWSKI.

Hydrocarbons

The Reactions of Pure Hydrocarbons
By Gustav Egloff. (American Chemical Society Monograph Series, No. 73.) Pp. xvii + 897. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1937.) 84*s.* net.

FEW men are more widely known or popular at gatherings of petroleum technologists than Gus Egloff, largely on account of his immense knowledge of his subject and his willingness to impart it to others. His research record is also second to none, so that a book from his pen is assured of a ready reception based on the expectation that it will prove to be of outstanding utility and interest.

The teaching of organic chemistry began for most of us with the paraffin hydrocarbons, though as we progressed we took but little interest in their chemistry. It is the conversion of the oil industry into a chemical industry that has brought about their extensive reinvestigation.

Faraday's famous paper in 1825 on "New compounds of carbon and hydrogen obtained during the decomposition of oil by heat" introduced benzene to the world, and already in those days "The Portable Gas Co." prepared gas by decomposing a mixture of fish and vegetable oils. In the latter part of the last century, oil gas was successfully used in lighting railway carriages, being made by the Pintsh process from petroleum or shale oil by heating—what is to-day termed cracking. An early description of this process by H. E. Armstrong (*J. Soc. Chem. Ind.*, Sept. 29, 1884) summarizes what must have been some of the first experiments on the pyrolysis of hydrocarbons.

Of late years, the hydrocarbons have assumed a new aspect, since it has been realized that almost unbelievable quantities are naturally available all over the world, appearing as gases, liquids and solids. The outstanding progress made by the oil industry in marketing liquid products is well known; as a by-product of refining, it produces large volumes of hydrocarbons supplementing the billions of cubic feet of natural gas handled daily. Natural gas in favoured countries has replaced manufactured illuminating gas. A new industry which is growing up is based on using the hydrocarbons, particularly those which are unsaturated, as the raw materials of an ever-increasing variety of chemical syntheses, and by cracking the saturated hydrocarbons an unlimited amount of unsaturated raw material is available.

Egloff divides the hydrocarbons into seven groups, distinguished as paraffins, olefines, acetylenes, aromatics, cyclo-paraffins, cyclo-olefines and terpenes. Although each group is individual in properties, it can be produced from, or converted into, most of the other groups under varying and to a high degree controllable conditions generally involving pyrolysis. Such processes have become of technical importance.

The seven main chapters of the book deal with the reactions of these groups, which are subdivided again under the individual hydrocarbons of the homologous series. Egloff uses the words "pure hydrocarbons" in his title, the justification being that the technique has progressed so far that in most instances complete separation is possible though the hydrocarbons are obtained in complex mixtures.

Theoretically, any organic compound may be prepared from its parent hydrocarbon, so that for the future a cheap source of this parent will give a great impetus to the development of synthetic organic chemicals: this is indeed likely to happen.

Inasmuch as paraffins are more susceptible to thermal than to chemical treatment, chief interest is attached to their decomposition both in the laboratory and in the factory when they are being transformed into more reactive unsaturated hydrocarbons. Hence the importance of an accurate knowledge of their decomposition reactions. The olefines are studied largely from the point of view of their susceptibility to polymerization, rearrangement to isomeric hydrocarbons and decompositions.

Acetylene has characteristic properties due to its unsaturation and high negative heat of formation, which enables it to polymerize into simple or complex molecules, such changes being facilitated by catalysts. Acetylene will be the source of many new substances, such, for example, as duprene (neoprene) the new synthetic rubber material. As yet, the higher acetylene homologues have been but little studied.

The reactions of benzene and its homologues bring the average chemist on familiar ground; here Egloff deals in detail with the theory and mechanism of their pyrolytic reactions.

The naphthenes or cyclo-paraffins have been much less studied though very large quantities are available. The 100 pages of this chapter are full of information not easily available elsewhere: some day these compounds will be put to specialized uses.

The final chapter concerns the terpene hydrocarbons present in the essential oils of plants whereas the other hydrocarbons described are of mineral origin: there are terpenes in certain mineral oils. The major industry connected with terpenes is that of turpentine and resin. Great interest attaches to isoprene, the unit hydrocarbon of rubber. Egloff has been at pains to collect the information relating to the thermal decomposition and polymerization of this group.

The magnitude of the work is evidenced by the fact that the subject and author index occupy 44 pages in double column. Its utility is unquestionable, it is veritably a master work, and future workers all over the world will be obligated to its author ; indeed it will undoubtedly accelerate the development of the subject experimentally.

E. F. ARMSTRONG.

Agents affecting Plant Growth and Movement

Der Einfluss einer Pflanze auf die Andere, Allelopathie

By Prof. Hans Molisch. Pp. viii + 106. (Jena: Gustav Fischer.) 4.50 gold marks.

IN this book, Prof. Molisch published shortly before his death an interesting account of a number of experiments he carried out to examine the effect exerted by one living plant upon another. His investigations do not deal with the so-called autogenetic radiations of Gurwitsch, of which he is a little sceptical, but have their starting-point in the known fact that, if early and late maturing apples are stored in close proximity, the latter arrive at maturity earlier than if they are stored separately. The same effect has also been observed in the case of pears. As it is known that ethylene is produced in the process of respiration of ripening fruits, it is probable that ethylene vapours are responsible for this phenomenon. Indeed Elmer, Huelin, Gane and other workers of the Food Investigation Board have not only proved the ripening effect of these ethylene-containing vapours of apples and other fruits, but have also shown that they inhibit the sprouting of potatoes and the growth of pea seedlings (see Gane, NATURE, 134, 1008; 1934). Experiments by Crocker in the United States have shown that epinasty of leaves can be induced by ethylene, and E. M. Harvey has determined the effect of ethylene on plant metabolism.

Molisch's experiments were concerned with the growth of seedlings exposed to the natural emanations from maturing apples, pears, oranges, lemons and bananas. Using the seeds of peas and vetches he found that, by placing a few apples in the closed vessel containing the germinating seeds, the growth of the seedlings was considerably retarded. Instead of attaining a height of 12–16 cm. in five days in a water culture, the peas seedlings had only grown 3–4 cm. in height. Grown in sand, the difference was even more striking. A further experiment showed that if the seedlings were exposed to the effect of maturing apples for only 1–5 hours their growth was actually stimulated, their height being 10 cm. when exposed for 1 hour and 9·5 cm. when exposed for 5 hours as compared with 7 cm. in pure air. The gas in dilute concentration evidently acts as a stimulant, agreeing in this respect with certain other organic poisons like morphine and amygdalin. The effect of other maturing fruits was of a similar retarding nature and in addition, as in the case of apples, they produced curious curvatures of the stem.

Epinastic curvatures of the leaves of growing plants, for example, *Solanum* and *Bœhmeria*, were also observed, and in other cases (privet and *Mimosa*) the proximity of apples produced leaf-fall.

The book contains further interesting records of the effect of ripening apples on the growth of roots, on the formation of callus, the development of lenticels, on the growth of pollen tubes and of fungi.

As it is known that roots excrete certain organic acids and also carbon dioxide, Molisch carried out some experiments with the roots of horse radish, carrot and beet and found that they had a slight stimulating effect on the growth of seedlings, but if the roots were cut longitudinally into four pieces they retarded growth. A considerable stimulus to growth was exerted by the root system of *Melaleuca squamea* and *Acacia verticillata.*

The effect of the proximity of vegetative shoots on the growth of vetch seedlings was to retard their elongation to a greater or less extent, while flowering shoots and particularly the flowers themselves inhibited growth in length very markedly. The inflorescences of the lilac had a deleterious effect on the growth of tomato seedlings.

At the end of the book, Molisch discusses the possible importance to the plant of the production of ethylene. Since he had shown that it retards the development of the mycelium and sporangia of *Phycomyces,* he concludes that it may prevent or at any rate delay the rotting of the fruits. On the other hand he is inclined to accept the view of Crocker that it may act as a fruit-ripening hormone. He points out that its action has much in common with such a growth-promoting substance as hetero-auxin. It causes similar epinastic curvatures, it delays the opening of buds and promotes the development of callus in poplar and the production of roots in cuttings of willow.

These undoubted resemblances between ethylene and some of the plant hormones are certainly very suggestive, and it is to be hoped that Molisch's book may lead to further researches in their elucidation.

Naturgeschichte der nordatlantischen Wale und Robben

Von Prof. Dr. Ernst Hentschel. (Handbuch der Seefischerei Nordeuropas, herausgegeben von H. Lübbert und E. Ehrenbaum, Band 3, Heft 1.) Pp. v + 54 + 10 plates. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung (Erwin Nägele), 1937.) 15 gold marks.

THIS is a comparatively small new part of Lübbert and Ehrenbaum's indispensable handbook of the North European fisheries. It is by Dr. Ernst Hentschel, known to us by a useful book on the marine mammals, published twenty-five years ago.

Here we have, in some fifty pages, a brief but sufficient account, well and copiously illustrated, of all the whales, dolphins, seals and walrus which inhabit the North Atlantic region, and have in some cases a wider, even a world-wide, distribution. All the great whales come into the story except the Californian Grey; and even that is said by some to have reached European coasts in former days.

Here and there the book seems to miss something. The herds of Ca'ing whales are mentioned at the Faeroes, but not at the Orkneys, though to them these islands owe their very name; Murie's paper on the same small whale is mentioned, but not his fine monograph on the walrus; the large walrus skull in Fig. 43 looks suspiciously like the Pacific variety; the peculiar teeth of the porpoise, so easily distinguishing it from all the other dolphins, are not mentioned; and the figure of the "gestreifter Delphin", whose "Rücken ist mit einer Anzahl unregelmässiger heller Streifen gezeichnet", merely shows, unless we are greatly mistaken, the scars of a recent encounter with a cuttlefish. D. W. T.

Univers 1937:

quelques aspects de l'astronomie contemporaine. Par Prof. Paul Couderc. Pp. xii + 182 + 12 plates. (Paris: Les Éditions rationalistes, 1937.) 20 francs.

THIS work serves a double purpose. Almost entirely devoid of mathematical formulæ, it is accessible to general readers who are interested in astronomy, though practically ignorant of its most recent developments. Nevertheless, the author has never dealt with any subject in a superficial manner, and it is amazing how he has condensed into such a small space the results of modern research, while still maintaining accuracy and precision in his descriptions. In the work we find all the most up-to-date information on nebulæ, stellar spectra, galactic rotation, proper motions, the expanding universe, the age of the universe, novæ, cosmic clouds, etc. Prof. Couderc has kept very closely in touch with every phase of the subjects, which he handles with consummate skill and with wonderful clarity in his descriptions.

The book is illustrated by ten plates, some of which are due to the first telescope installed at Forcalquier, the future astrophysical station in France. Altogether we have found it a most readable work. M. D.

Astronomy for the Layman

by Frank Reh. Pp. xviii + 308 + 16 plates. (New York and London: D. Appleton-Century Co., Inc., 1936.) 12*s*. 6*d*. net.

THIS work is intended for the average reader who has little knowledge of astronomy, and is written in simple and non-technical language. Some may wonder why the author commenced with the sidereal universe and ended up with the solar system; but this is a minor point which will be lost sight of in the clear and interesting presentation of salient matters in astronomy. In the foreword by Dr. Clyde Fisher reference is made to the wealth of poetical quotations which appear in the different chapters, and many will be grateful for this anthology, ranging from the days of Hebrew cosmogony up to modern times.

A considerable portion—nearly one hundred pages—is devoted to descriptions of the constellations, with numerous diagrams. There are also many illustrations and photographs in the text. The book should stimulate readers to pursue more fully the subjects dealt with in the cursory fashion which is inevitable in the wide survey taken by the author. In the very brief discussion of various matters it is impossible to avoid expressions which may be misleading. Thus, on p. 235, readers might gain the impression that the moon is approaching the earth at present, owing to tidal friction. It is true that our satellite will some day approach us after it has receded a long way from its present orbit, but it is not approaching us now. In Chapter xvi there is little or nothing to show the distinction between the planetismal theory of Chamberlin and Moulton and the tidal theory of Jeans and Jeffreys. These are minor blemishes which do not detract from the value of a very interesting work. M. D.

Electron Tubes in Industry

By Keith Henney. Second edition. Pp. viii + 539. (New York and London: McGraw-Hill Publishing Co., Ltd., 1937.) 30*s*.

THE author is not so much concerned with fundamental scientific ideas as the practical application of electronic devices, and he does this very thoroughly, with ample references to original literature. The general characteristics of vacuum, gaseous, and photo-sensitive tubes are explained and suitable applications indicated, some of which are surprising. The text forms an ideal reference book and should be widely known. L. E. C. H.

The Methodology of Educational Research

By Prof. Carter V. Good, Prof. A. S. Barr and Douglas E. Scales. (Appleton Series in Supervision and Teaching). Pp. xxi + 882. (New York and London: D. Appleton-Century Co., Inc., 1936.) 16*s*. net.

A SURVEY of the chief methods used in educational research, together with a list of those problems which the authors consider suitable for university research workers.

America Revisited

By Dr. G. W. C. Kaye, O.B.E.

EVEN in depressed times, America is a stimulating country to visit, and I found the present national outlook a good deal more subdued than on the occasions of my previous visits; one, ten years ago at the height of a boom period, the other, during the Great War. Even so, the public and industrial activities of the United States seem to have lost little of their customary courage. San Francisco, lacking a site for its projected International Exhibition in 1939, has not hesitated to create one in the shape of an artificial island, some 400 acres in extent, in the middle of the bay. Not content with this, the city has just spent twenty-three million pounds in four years on two large new bridges, one of them, across the Golden Gate, having a record span of 4,200 feet. New York City is building at monumental expense a new elevated high-speed roadway along the water-front of Manhattan Island to try to relieve the traffic congestion, while Los Angeles is constructing road tunnels with the same object.

Americans, one gathers, pride themselves on owning more cars than any other nation. Traffic problems in the big cities are proportionately acute: it appears that on a normal weekday a quarter of a million cars enter New York and leave it, and that in the early afternoon some 35,000 cars are parked in busy streets. Incidentally, no lights are required on cars parked in American streets at night. There are relatively few buses and most of the passenger traffic in New York is carried by the 'subway' (underground). This is cheap (2½*d.* everywhere), noisy, foul but fast, and the rush-hour scenes are incredible. The elevated railways in both New York and Chicago are an unmitigated eye-sore and a noisesome blight upon the unfortunate streets which hold them.

Thousands of miles of magnificent highways, beautifully graded and cambered, have been built all over the States, largely by 'volunteer' battalions as a palliative for unemployment. Dual tracks and flying junctions lead to high cruising speeds—60 m.p.h. or more seemed to be commonplace. The published annual death-roll from motor accidents in the States is considerably higher than with us—it was nearly 40,000 in 1937, that is, nearly twice as large as ours in proportion to the population.

The roads in residential areas gain in attractiveness from the American custom of no fences in front of houses. It follows that there is little or no privacy in the gardens or "yards", but none is apparently desired. The Americans have a great aptitude for coining words; 'mortition' I knew of old, but 'beautician' must have come in with the countless beauty parlours.

Continuous demolition and rebuilding and disorganized streets seem to delight the New Yorker, who regards them as a sign of progress and doesn't mind being a little late to-day for the sake of being a little early to-morrow. New Yorkers claim, too, with no apparent contrition, that they possess the noisiest street corner in the world. Public apathy recently helped to terminate the existence of the Noise Abatement Commission. In a room on the sixteenth story, I found the noise of the elevated railway nearby was intolerably loud. On the twenty-seventh story it was beneficial to shut the windows, when telephoning, in order to cut out the rumble of the street traffic.

Most American cities seem to possess skyscrapers, partly in emulation, one supposes, of New York, where the newer skyscrapers are really beautiful by day, and almost fairylike by night when floodlit or when picked out by the lights of the windows of the occupied rooms. I noted, incidentally, that the express elevators usually allowed one second per floor (though sometimes less) whether going up or down. The tall isolated buildings of the new Rockefeller Centre and Radio City, which occupy some 12 acres, arrest attention by their dignified grouping.

Air-conditioning, which one finds in public rooms throughout the States, is a valuable addition to the amenities of railroad travel, particularly in the warmer south. The cooled and filtered air enters from the roofs of the coaches, the chilling being effected either by ice or by refrigerators, and the filtering by asbestos mats or the like. Some of the transcontinental railways run high-speed 'limited' trains on certain days in the week, largely to meet the growing competition of air travel, which is well organized and popular, being well suited to the great distances. In Canada the air carriage of freight, which already greatly exceeds that of any other country, being one third of the total for the world, is acclaimed as an outstanding boon for the widely scattered settlements.

Public interest in scientific matters appears to be high: popular scientific and technical journals of many and varied types cater in abundance on the bookstalls for the multitudes of young men who want to make good in the world. Public lectures gather large audiences, and no public dinner or luncheon is apparently complete without a post-prandial lecturer, who will find himself attentively and closely followed. Uplift movements of all kinds receive the enthusiastic support of the women, whose domestic arrangements seem to afford them more leisure than with us. There is a strong and growing movement, so I was told, for a five-day week for all classes of workers, though I should hazard that, class for class, the men work longer hours per day than in Great Britain. Their leisure is never too scanty, however, to prevent their showering on the English traveller kindly and proverbial hospitality: it is impossible to acknowledge their friendliness to England too appreciatively.

New York abounds with interest for the visitor with scientific leanings—Columbia University, the Bell Telephone Laboratories, the National Broadcasting Co., the 'Long-Distance' building for telephone and radio-telephone circuits. Everywhere one experienced boundless keenness, enthusiasm, knowledgeability, and friendliness.

The two capital cities of Canada and the States well repay a visit. Ottawa, which is being subjected to a measure of replanning, occupies a site of great natural beauty. Among the recent buildings are the palatial National Research Laboratories which, finely situated on the bank of the Ottawa River, are playing an ever-increasing part in Canada's industrial affairs. Washington must surely be one of the most beautiful cities in the world, with its stately buildings and wide avenues bordering on the Potomac River and Park. White marble and Greek architecture are adhered to for public and Governmental buildings in the environs of the Capitol, among the more recent additions being the magnificent Supreme Court and the Folger Shakespeare Library with its replica of the old Globe Theatre. The dignified building of the National Academy of Sciences stages permanently a fine series of working exhibits of fundamental experiments, which the public eagerly frequents. Some four miles away is the National Bureau of Standards, sister institution to the National Physical Laboratory, and with many problems in common.

Western America provides a powerful magnet for the visitor, in the shape of the Canadian Rockies, the Yosemite Valley, the Big Trees, the National Parks, the Grand Canyon, and the gracious beauty of San Francisco where the delightful climate, sea fogs and western geniality make an Englishman feel thoroughly at home. At Berkeley, a few miles away, the University of California exemplifies the scale of grandeur on which so many of the American and Canadian universities have been established. Among much that is intriguing are the full-scale daily newspapers which the students control, finance, publish and edit at some of the universities. Berkeley rejoices in a fine campus and many magnificent buildings, including a Greek theatre holding 10,000 and a sports stadium for 90,000. It is here that E. O. Lawrence by his genius and persistency has developed the cyclotron into the most potent practical contribution of recent times to the study of neutrons and artificial radioactivity. I refer to this again later. Thirty miles south at Palo Alto, is the Leland Stanford University, the buildings of which are most attractive with walls of buff-coloured sandstone and red-tiled roofs in the old Spanish mission style. Among much else of interest is a 2 million-volt transformer outfit, the insulating supports of which were braced with temporary steel strutting. This, I learnt on inquiry, was a precautionary measure in readiness for the next great earthquake, which was about due!

Los Angeles, that city of astounding growth and spacious conceptions, confronted with the problems of overcoming desert conditions, has solved them with gigantic irrigation schemes. Water is distributed lavishly: lawns are only kept alive by almost continuous sprinkling. Fruit is amazingly cheap. Here are the fine new buildings of the University of California, the University of Southern California, and the renowned and immense film studios of Hollywood, a city which merges completely into Los Angeles. Near by is the 'Hollywood Bowl'—a natural hillside auditorium capable of holding forty thousand people and possessing marvellous natural acoustics, which are reinforced by a large 'shell' reflector enabling those in the remotest seats 550 feet away to hear easily. The Bowl is famous for its "Symphonies under the Stars". The stable and agreeable climate enables outdoor social functions to be held with certainty.

Ten miles away near the hills is Pasadena, with its famous California Institute of Technology. Among much of interest is the Kellogg radiation laboratory where Dr. C. C. Lauritsen's pioneer work on super-voltage X-ray therapy is being carried out. In another building one can see the process of grinding the 200-inch reflector which, when completed in about two years' time, is intended for Mount Palomar, a hundred miles away, as the night glare of Los Angeles has grown to interfere with some of the work at Mount Wilson. Incidentally, there is now a magnificent road up to the 5,700-ft. summit of Mount Wilson, the journey by car from Pasadena taking about an hour, a very different state of things from that which prevailed a few years ago. The Observatory lays itself out to attract visitors, some twenty thousand attending the lectures and demonstrations during the year. A similar public response meets the efforts of the Observatory in Griffith Park, overlooking Los Angeles, visitors flocking to see the planetarium and astronomical working models.

While much of Chicago is drab and drear, the new and reclaimed portion on the shore of Lake Michigan is remarkably attractive. In September last at Chicago, the Fifth International Congress of Radiology, with some 2,800 members from forty nations, held its meetings and housed its members in a single hotel equipped with suitable convention halls and some two thousand bedrooms. Under the efficient presidency of Dr. A. C. Christie of Washington, several hundred papers were down for reading : they were dealt with by nine different sections, which met concurrently, apart from a few general sessions. The enthusiasm of members was catered for by programmes of meetings and educational courses which, together with intervals for sustenance, went on daily from 8 a.m. until midnight or after. Any unemployed moments could be devoted to a large scientific and industrial exhibition of apparatus. Many examples of shock-proof high-voltage X-ray apparatus were on view, together with associated devices designed primarily for the study of neutrons and nuclear physics.

The radiophysics section was mainly devoted to the measurement and generation of very short wave radiation, that is, X-rays generated by voltages of the order of a million volts, and radium gamma rays. Some of the papers were of extreme interest. As regards the production of very high voltages, America, always a pioneer in such matters, is now paying widespread attention to the use of super-voltages, not only for nuclear physics research, but also for X-ray therapy for cancer treatment. As against radium therapy, the arguments advanced are that it is not yet proved or ruled out that the shorter gamma rays have any clinical advantage over X-rays, while the latter, though bearing higher maintenance charges, offer the advantages of a lower initial cost and the possibility of implanting greater depth doses in the body. There appeared, however, to be a considerable body of opinion which doubted whether there is as yet any sound clinical evidence which could establish a real superiority of million-volt X-ray therapy over, say, 200 or 400 kv. therapy.

Quite apart from the achievements of the high-voltage electrical engineer for commercial utilities, there have recently been developed for physical and clinical purposes a number of radically different methods for generating very high voltages : (*a*) the super-tension transformer, (*b*) the radio-oscillator generator, (*c*) the electrostatic generator of the belt type, (*d*) the cyclotron.

Million-volt transformers of which some part or other of the high-voltage circuit is in the open air, are of necessity so large as to require a special building to house them ; there are numerous examples operating X-ray tubes, neutron tubes, etc., mainly in the States, but also elsewhere. The principle of mounting both transformer and X-ray tube in a common oil tank has long been familiar, but it has now been extended to voltages of 400 kv. and upwards. In a recent development of high-voltage X-ray apparatus by Dr. Coolidge, only the earthed target-end of the tube emerges from the tank. The advantageous features of this type of outfit are the freedom from electrical dangers, the relatively small amount of lead protection required, the accessibility of the target, and, perhaps, most of all, the small space needed, the dimensions of the outfit being of the order of only a few feet. Recent experiments on the replacement of transformer oil by compressed gaseous dielectrics are likely, it is anticipated, to lead to high-tension generators of even more modest dimensions.

Examples of radio-oscillator resonance X-ray generators, designed by Dr. D. H. Sloan, are to be found in New York and San Francisco. A short-wave radio oscillator sends its power into a high-voltage resonance coil mounted within a metal vacuum tank which serves as the X-ray tube and which is continuously evacuated. The hot cathode is situated in the side of the tank directly facing the X-ray target, which is mounted on the bottom of the coil where there is a voltage maximum, so that the high voltage is generated entirely within the X-ray tube precisely where it is to be used.

Electrostatic machines were largely used in the early days of X-rays, and the electrostatic high-voltage generator of the endless-belt type, which we owe to Van de Graaff, is virtually a large Holtz machine, consisting essentially of a rounded conducting terminal supported on an insulating column and charged by a swiftly moving (4,000–5,000 feet a minute) flat insulating belt (of rubberized fabric) conveying electricity 'sprayed' on the belt by corona points charged with 20,000 volts, and depositing it within the terminal. The outfit is robust and simple, and very high and steady voltages (several million) may be obtained. The current output is proportional to the speed and number of the belts and the dielectric strength of the surrounding medium, usually air. There are now a number of these installations in the States ; I saw an early type at the Carnegie Institution (Dept. of Terrestrial Magnetism) at Washington. This produces a million volts with regularity : the only uncertainty is occasioned by the high humidity which often occurs in Washington. This difficulty will be avoided in the new 5 million-volt apparatus which is being constructed, and which will operate at several atmospheres pressure within a large pear-shaped steel reservoir (some 60 or 70 feet high), mounted vertically on its small end. This outfit is designed for work on nuclear physics. Another outfit at the Huntington Memorial Hospital, Boston, operates a continuously pumped cascade X-ray tube at a million volts and up to three milliamperes; while yet another outfit, at the Massachusetts Institute of Technology, develops a steady voltage of five million and a current of two milliamperes in work on atomic disintegration.

The cyclotron was designed for use in the domain of atomic physics and, while it is inapplicable at present to X-ray purposes, it does, as already mentioned, render available for the biological worker and radiologist two powerful new tools, in the shape of artificial radioactive elements and neutrons. Some twenty-five outfits are at present under construction the world over, six or seven in the States and two in England (Cambridge and Liverpool).

The latest model of the cyclotron, which incidentally weighs 100 tons, utilizes the principle of multiple or 'cascade' acceleration of ions by a combination of a magnetic and a swiftly alternating electric field, and can so impart to a beam of protons or deuterons equivalent voltages up to 7½ million. If the beam is allowed to impinge on beryllium, a stream of neutrons results which may be some thousands of times more powerful than any other method can provide. For example, a beam of neutrons corresponding to 7½ million volts and 20 microamperes is stated to be equivalent to the gamma radiation from 100,000 grams of radium in equilibrium. The controls for the operator are remotely situated from the cyclotron, further protection being afforded by tanks of water three feet thick encircling the apparatus.

By the use of one or other of the three types of particle which the cyclotron provides in such abundance, virtually all the known elements have been made to yield radioactive isotopes through the method of nuclear bombardment. Among them is radio bismuth, which is identical with radium-E in every respect. In one day as much radio sodium (with a half-life of 15 hours) can be made as corresponds to 100 mgm. of radium. Some of the artificial radioactive elements are finding a revolutionary field of service as 'tracers' or 'tagged atoms' in biological and clinical research. For example, radio sodium, when drunk in a solution of common salt, manifests itself in the fingers of the hand in less than two minutes by the emission of gamma rays; the residue, magnesium, is quite innocuous within a few days.

Both in Berkeley and elsewhere the study of neutron therapy (on animals) is being taken up. Neutrons ionize in a manner very different from that of gamma or X-rays, and are unique in being more absorbable in body tissue than in bone. If the present claims of selective reaction to tumour tissue are substantiated, it would seem that neutrons may presently have high therapeutic significance.

Prof. Lawrence has under construction a special building for housing a much larger cyclotron, which has been designed expressly to generate radioactive elements for prosecuting bio-physical and medical research. The new outfit, which will weigh 220 tons, is expected to afford voltages equivalent to 10 million, and to give five or ten times the yield of the present cyclotron.

It is the practice of the International Radiological Units and Protection Committees to meet on the occasions of the International Congress. The chief business before the Units Committee, which met under the chairmanship of Dr. Failla of New York, was to determine whether or not the time had come when the röntgen—the ionization unit of X-ray quantity—should also be used for very high-voltage rays and radium gamma rays. The British delegates (Dr. N. S. Finzi, Prof. F. L. Hopwood and Dr. G. W. C. Kaye) presented a memorandum from the British X-ray Units Committee, which advocated the step and with it an appropriate modification of the present definition of the röntgen. In the end, the important step was taken and a generalized definition was agreed provisionally until the next Congress, when it was anticipated that a still more general definition embracing all classes of radiation may be forthcoming. The röntgen is now defined as follows: "The röntgen (symbol r) shall be the quantity of X- or gamma-radiation such that the associated corpuscular emission per 0·001293* gramme of air produces, in air, ions carrying 1 electrostatic unit of quantity of electricity of either sign."

The International Protection Committee, which met under the chairmanship of Dr. Kaye, made a number of changes in the existing recommendations, particularly in relation to the new problems of protecting operators working with super-voltage X-rays or radium 'bombs' containing large quantities of radium. Many of the data utilized were based on recently published results of the National Physical Laboratory.

It was announced during the Congress that the next meeting would be held in Berlin in 1940 under the presidency of Dr. Holthusen of Hamburg. It will be governed by a new set of rules and regulations adopted at Chicago, largely through the energy and initiative of Dr. Christie.

---

* 0·001293 gramme is the mass of 1 c.c. of dry atmospheric air at 0° C., and 76 cm. of mercury pressure.

Quaternary Glaciations in Central China

DR. J. S. LEE, the well-known Chinese geologist, has sent to the Editor of NATURE the proofs of a monograph entitled "Quaternary Glaciations in the Lushan Area, Central China" with a series of photographs, intended in the first place for publication in vol. 2, ser. B, of *Academia Sinica*. Its transfer to England by air transport, with the request that it be placed in the safe custody of a responsible geological institution, conjures up a lively sense of the present and future state of affairs in China; which aspect, however, has no part in this article except in its bearing on the future publication of the monograph. Another aspect, and one having some significance, is that one would scarcely expect Dr. Lee to take such care to ensure the preservation of this material and to have it brought to the critical notice of expert glacialists, if he were not confident of the prime importance of his latest investigations in the Lushan mountain massif.

A few words of explanation are perhaps necessary to a proper understanding of the latter remarks. The very existence of evidences of glaciation in Central China has in the past been questioned by many geologists with experience of glaciated districts. When Dr. Lee in 1934 published his first account of the 'Boulder Clays', striated rocks, transported blocks, etc., in the Lower Yangtze Valley, and invoked true glaciation (as against solifluxion and allied phenomena) to explain the facts, his evidence was challenged by G. L. Barbour after a cursory joint traverse of the ground.

Barbour, while admitting the extraordinary character of many of the deposits, sought to identify them with long periods of abnormal subærial weathering and erosion, possibly commencing so far back as early Pliocene or even Miocene times. The clay matrix of the 'Boulder Clay' was likened to non-glacial loam; the presence of boulders he explained as due to sinking into the leached soil of laterized surface rocks followed by gradual descent to lower ground under gravity; while a theoretical series of structural events was postulated to account for the presence of transported blocks in elevated positions relative to their apparent source. Further, an absence of (1) glacial sculpture, (2) glacio-fluviatile deposits, and (3) *roches moutonnées* was claimed by Barbour, though it was admitted that shortage of time prevented his seeing many crucial features.

At that time (1934), Barbour was clearly inclined to the belief that the glacial explanation of the Lushan phenomena was not acceptable. Yet he paid high compliment to Lee for "his penetrating recognition of the possible significance of this extraordinary geological occurrence", admitting further that the last word on the matter had not yet been said and that his (Lee's) interpretation had not been disproved.

That Dr. Lee was not deterred by these criticisms from a geologist of wide experience is shown by his energetic pursuit of confirmatory evidence, and the monograph under consideration directs attention to this glacial evidence under the headings (*a*) geomorphological indications; (*b*) moraines and their associated deposits; (*c*) striated rocks. A short account of the bed-rocks of the Lushan is given to enforce the arguments dealing with transported blocks; and more ambitious inferences than previously attempted are introduced to demonstrate a three-fold glaciation of the Yangtze valley.

A well-contoured map of the Lushan, bounded on the north by the Yangtze River and on the east by the Poyang Lake, accompanies the monograph. It shows the geographical extent of the glaciations and includes the observed indications of fluvio-glacial deposits, terminal and lateral moraines, drainage channels, glacial striæ, and striated boulders. The scale of the map is 1 : 50,000.

A critical review of the monograph is thought to be undesirable here. For it is clear that, failing an intimate knowledge of the area, an unquestioning acceptance of the validity of the glacial terminology must precede any attempt to estimate the full value of the evidence. This assumption is supported by the fact that G. L. Barbour, well experienced in low-latitude glacial phenomena, was unable to put forward final and convincing conclusions regarding the Lushan deposits and allied features. Attention will therefore be confined to a summary of the chief points of interest raised by Dr. Lee. Glacial geologists, by permission of the Editor of NATURE in arrangement with the Director of the Geological Survey and Museum, will be afforded the opportunity of consulting the monograph and map at the Survey Library, where the documents are being housed pending further instructions from Dr. Lee.

In his analysis of the glacial evidence, Dr. Lee stresses the fact that landforms have suffered extensive erosion and consequent modification since the last glacial period. The geomorphological indications are therefore not in themselves conclusive; but they were sufficient to inspire Lee and induce him to search for other signs of glacial

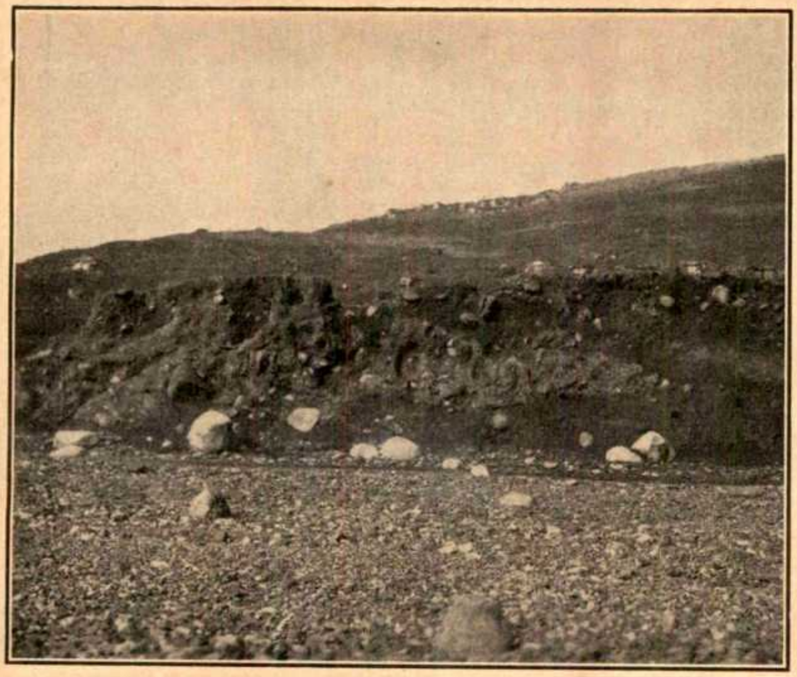

Fig. 1.

A LENTICULAR MASS OF HARDENED AND LATERIZED BOULDER CLAY OF THE POYANG PERIOD INVOLVED IN THE LOOSER BOULDER CLAY OF THE TAKU PERIOD, NEAR THE KUTANG VILLAGE.

but along the side of it." The ravine begins abruptly in front of a mass of Boulder Clay "which proved to be the remnant of an end moraine", and here is a slight similarity to certain drift-diverted streams and gorges in Lancashire. Another case of drainage which suggests the former existence of a valley glacier is described from the Chilichung Valley.

In connexion with several dry gaps which have been cut into the north-western ridge of sandstone in the Lushan, the statement that "the only feasible explanation of the origin of these gaps seems to be that they were produced by spills from the glacier" is supported by acceptable evidence. Examples are also given, though with varying assurance, of firn basins, corries, and kindred features; more confidence is expressed in the phenenoma. The frequent occurrence of rock basins on the top and flank of the northern part of the Lushan is noted, but not accepted indiscriminately as evidence of glacial sculpture. A strong case, however, is made for a true cirque on the central heights at a spot where a circular depression is carved out of resistant rock of uniform composition, free from structural weakness. It has a fairly steep back-wall and hangs to a main valley in front; further examples on the south-eastern flank are also described.

A circumstantial account is given of the most striking example of a U-shaped valley seen in the area, namely, the Wangchiapo Valley. One feature is worthy of Lee's own words: "The question therefore arises as to whether the U-shape of the valley is not entirely due to the synclinal structure with the non-resistant Kuniuling rocks being more or less completely removed by stream erosion. That this is not entirely true is indicated by the behaviour of the existing streams and by the deposition of terminal moraines which still survive. . . . Here it suffices to note the occurrence of a deep ravine through which the stream pours down the valley. This feature has been incised by the stream and has attained a depth of no less than 70 m. below the floor of the valley at Wangchiapo. . . . Beds of the Wulafoeng Grit are thereby excavated in the form of a trench; and curiously enough, the trench does not run along the axis of the syncline or the lowest part of the valley bottom

case of two "zungenbecken" or "central basins" relics of piedmont glaciers on the north side of the mountain.

Coming now to the important matter of depositional evidence, that is, moraines, boulder-clay, etc., we are presented with an interesting story leading to the postulation of three glaciations, associated with three distinct types of boulder-clay. The two lowland types are illustrated in Fig. 1, which shows the incorporation of blocks of the earlier well consolidated dark red variety by the later brick-red less consolidated one. The latter is more widespread and has undergone less laterization. It is important to note, in view of Barbour's earlier objection that the boulders in the boulder-clay were invariably hard quartzites and grit, that Lee now emphasizes their lithological variety. Lateral and terminal moraines, a block moraine, and an outwash apron are instanced, though a fuller development of these is said to be lacking as a result of excessive, inter- and post-glacial destruction. Solifluxion has been found inadequate to explain the transfer of large blocks over the long distances required; the famous Poyang Lake section of glacial drift containing such boulders is 9 km. from their source in the Lushan, and the intervening pre-glacial gradient is negligible, yet is, according to Lee, demonstrably greater than in Boulder Clay times.

Finally, the scratched boulders and striated rock surfaces (Fig. 2) are claimed by Lee to be perhaps the most convincing evidence for glacial operation, and it need only be remarked that Barbour's scepticism on this matter must have created in Lee a strong urge to test this type of evidence very thoroughly. W. L.

Obituary Notices

Dr. G. E. Hale, For.Mem.R.S.

BY the death of George Ellery Hale on February 22, at Pasadena, California, solar physics loses its greatest leader. Born in Chicago on June 29, 1868, he had already in 1890, before completing his studies at the Massachusetts Institute of Technology, begun working at the Harvard College Observatory on his idea of a spectroheliograph. Resisting the temptation to accept Prof. Holden's offer of opportunities to develop his new instrument in connexon with the 36-in. refractor at the Lick Observatory, he established with his father's help a private observatory at Kenwood, in a suburb of Chicago. There, working in the fourth order of a 4-in. Rowland grating attached to a 12·2-in. equatorial, he studied the spectrum of the solar prominences and photographed them in monochromatic light, using first of all the bright K line of calcium. As he found by photographic spectroscopic observations that the bright K_2 line could be detected here and there on the disk of the sun, he extended his work to monochromatic studies of the whole solar disk, finding the presence of great areas of glowing calcium clouds in general around sunspots. By 1892, his pioneer work had won for him recognition by the University of Chicago, of which he became an associate professor.

Through the munificence of C. T. Yerkes, by no means the last wealthy man in whom Hale was to inspire confidence in his ability to make excellent use of large benefactions, he was given charge of the new Yerkes Observatory at Williams Bay, Wisconsin, with the largest refractor in the world (40-in.) and with the Rumford spectroheliograph, which gave him an image of the sun 6·5 inches in diameter. At the Yerkes Observatory with Barnard, Burnham and Frost to help him he worked steadily for nearly ten years on stellar spectra and solar problems. The next great instrumental development became possible for him in 1904, through the generous assistance of the Carnegie Institution, when he was made director of the Mount Wilson Observatory. Here he successfully developed the tower telescope (60 ft. and later 150 ft.) with underground spectrographs (30 ft. and 75 ft.) for solar work; for high dispersion stellar spectra and work on distant nebulæ the 60-in. and 100-in. reflectors were available, the latter being due to the munificence of J. D. Hooker. He gathered a great team of colleagues together, and the publication of the annual report of the Observatory became one of the major events of the astronomical year. Hale's own contributions were mainly on the solar side and included such outstanding discoveries as that of the intense magnetic fields in single sunspots, the existence of bipolarity in groups of spots of opposite polarity, the change of polarity of such bipolar spots after each sunspot minimum and the relatively weak general magnetic field of the sun (a full account of Hale's solar work is given in an article by Prof. H. F. Newall in the series of Scientific Worthies in NATURE of July 1, 1933, p. 1).

In 1923, under the strain of his many activities, Dr. Hale's health gave way and he retired from the active directorship of the Observatory to become honorary director. But his work was not done. On the observational side, he developed the spectrohelioscope, now a valuable instrument in the study of solar eruptions of short duration and of their reaction on the terrestrial ionosphere; on the administrative side he was mainly responsible for securing in 1928 the grant from the Education Branch of the Rockefeller Foundation, which made it possible to undertake the heavy task of constructing a reflecting telescope with a mirror 200 in. in diameter. Hale took a large share in the preliminary studies and work necessary for the successful completion of this project.

As an investigator, Hale did as much as one man could be expected to do. But his scientific activities covered a much wider range. As foreign secretary of the National Academy of Sciences he was active in establishing the National Research Council of the United States, of which he remained honorary chairman until his death. His international work in astronomy began in 1895 with the foundation of the *Astrophysical Journal*, following upon the publication three years earlier of *Astronomy and Astro-Physics*.

Then in 1904 at St. Louis came the foundation of the International Solar Union on Hale's initiative. President at its first meeting, he, with Schuster and Arrhenius, was elected on to its first executive committee, remaining a member of it throughout the life of the Union. In 1919 came the formation of the International Research Council with Hale as an active member of the original executive committee; later he became president for the years 1934–37 of the International Council of Scientific Unions. In the International Astronomical Union formed under the auspices of the Council, Hale was elected president of the Commission of Solar Physics (1919–25).

Honours and awards came to Hale freely from scientific bodies and universities all over the world. To mention only those from Great Britain, they included honorary degrees from Oxford, Cambridge and Manchester, medals from the Royal Institution and the Royal Astronomical Society, of which latter body he was an associate. Foreign membership was given him by the Royal Societies of Edinburgh and Dublin, by the Cambridge Philosophical Society and by the Royal Society, which in 1932 awarded him the Copley Medal, primarily for his work on magnetic fields in the sun.

F. J. M. STRATTON.

ANYONE meeting George Ellery Hale must, I think, have felt at once that he was somewhat out of the ordinary run of scientific men. We knew he was a great figure in science, but felt that he could have been equally great at almost anything else. For Nature had not only endowed him with those qualities that make for success in science—a powerful and acute intellect, a reflective mind, imagination, patience and perseverance—but also in ample measure with qualities which make for success in other walks of life—a capacity for forming rapid and accurate judgments of men, of situations, and of plans of action; a habit of looking to the future, and thinking always in terms of improvements and extensions; a driving-power which was given no rest until it had brought his plans and schemes to fruition; eagerness, enthusiasm, and above all a sympathetic personality of great charm. This great and varied array of talents gained for him the complete confidence of everyone he met, from the highest to the lowest.

I never ceased marvelling at his great knowledge of almost every department of observatory work. He was not only for many years director of the great observatory which was so largely his own creation, but also had made himself an expert in most of its varied branches; and I know from my own experience how genuinely he could interest himself in other people's scientific work and ideas, and how warmly and sincerely he could give encouragement.

It was a great tragedy that indifferent health so restricted his activities in the latter years of his life—his ever-eager mind and ardent spirit had made too exacting demands on a none too strong body; it is an even more poignant tragedy that he has not lived to see the completion of the great new telescope which will owe so much to his forethought and planning.

J. H. JEANS.

THE death of Dr. G. E. Hale, coming at the end of a slow decline of strength such as he has suffered since July 1936, can scarcely be regarded as other than a merciful release from protracted suffering. The sincere sympathy of his very numerous friends goes forth to his wife and family and relatives, and the memory of a very remarkable personality will be widely cherished.

His geniality and his interest in a wide extent of natural knowledge and of art and literature and history made him a very welcome companion.

Hale was in truth a leader not only in his own chosen investigations in solar physics but also in the initiation and furthering of organization of scientific co-operation. By a rare combination of personal qualifications of which he seemed to be entirely unconscious, he achieved early in life recognition of his power to evoke enthusiastic support in developing available resources for the advancement of natural knowledge. In 1890 he had resisted an offer of the director of the Observatory on Mount Hamilton in California, an offer that he should have the use of the Lick refractor during stated hours in the week for the development of his spectroheliograph. Fortunately, through the wise advice of his father, he decided to utilize full time with a 12-in. refractor specially constructed at the expense of his father. After a couple of years of successful observations in the Kenwood Observatory he was called upon to take charge of the new observatory in Wisconsin, where a finished product of the workmanship of Alvan Clark in the form of a 40-inch achromatic objective, which Hale's enthusiasm had induced Mr. C. T. Yerkes to purchase, was to be mounted in the Yerkes Observatory of the University of Chicago.

In 1904, Hale received noble encouragement from the trustees of the Carnegie Institution to found a Solar Observatory in California, and there he began that very notable succession of advances based on experimental trial on relatively small scale and leading to successively increased power of instrumental equipment on novel lines. Aided by funds contributed by the Carnegie Institution, by Miss Snow, by Mr. J. D. Hooker, by the Rockefeller Foundation and probably also by other sources, there arose on Mount Wilson the observatory provided with extensive workshops and physical laboratories and devoted to the intensive study of all branches of astronomy and many branches of physics.

There, under the stimulating influence of Hale in the encouragement of team work, not only were opportunities of a very unusual kind afforded to the members of the devoted permanent staff, but also welcome was extended to students of recognized authority from all parts of the world, to join in co-operative work.

Even in the resulting activity, Hale himself found time and energy to produce very notable scientific contributions, such as his splendid discovery (based on Zeeman's discovery of the influence of a magnetic field on spectral lines of a gas rendered luminous in such a field) that sunspots were the seats of violent magnetic phenomena and that the sun showed signs of having a general magnetic field, with poles not far removed from the poles of the axis of the sun's rotation. One of his latest achievements was the invention of his beautiful spectrohelioscope for visually studying local changes of short duration in the features of the sun's surface—a study that seems likely to throw light not only on the cosmical origin of terrestrial magnetic storms and of the aurora borealis, but also on certain peculiar phenomena encountered in the reception of wireless signals, which seem to indicate the arrival of external influences (probably of solar origin) in the outer atmosphere of the earth.

Truly Hale was a leader of outstanding ability, and his influence and memory will long be cherished. His many friends will join in a deep regret that it was not given to him to live to see the completion of that huge enterprise of the 200-in. reflector, in the initiation of which he took so deep an interest.

H. F. NEWALL.

THE most prominent characteristics of Dr. Hale were his whole-hearted devotion to astronomy and his friendship with his colleagues and fellow workers. His invention of the spectroheliograph and spectrohelioscope and his discovery of the magnetic field in sunspots are tributes to his mechanical genius and insight. The two magnificent observatories and the 200-in. telescope are outstanding achievements. But he had also a very catholic interest in the work of his colleagues all over the world, and was always ready to give them help. The Solar Union had Hale for father and, as wittily said by a German astronomer, Schuster for mother. He attached great value to good fellowship among astronomers, amateur and professional alike, for the advancement of the science.

I shall always remember the times I have met Hale and the complete absence of any superiority or what is vulgarly but expressively called 'side'. The last occasion when I saw him was some seven or eight years ago, when he invited Sir Herbert Jackson, Prof. A. Fowler and me to lunch, and we heard of his project for the 200-in. reflector. Another time he was passing through Edinburgh after a visit to Andrew Carnegie at Skibo Castle, and was hugely delighted at having beaten Andrew at golf and caught a bigger fish. He was a great man, and I, with many more, am proud to have been among his friends.

F. W. DYSON.

Mr. C. Green

THE death of Charles Green, chief inspector of fisheries in the Fisheries Branch of the Department of Agriculture of Eire, on February 9, after a short illness, came as an unexpected shock to his friends.

He was born in 1876, the only son of the Rev. William Spotswood Green, a well-known alpine climber and organizer of deep-sea trawling expeditions, and was educated at St. Edward's School, Oxford. After taking a degree, with a gold medal in natural science, in Trinity College, Dublin, he was, in 1900, appointed a naturalist on the staff of the newly constituted Fisheries Branch, afterwards becoming inspector and, later, chief inspector.

Though his official duties tended to direct his attention more to the legislative and administrative side of fishery affairs, of which his knowledge was extensive and profound, Green kept in close touch with recent biological research, and it was due largely to his insistence that the dictum, laid down by his predecessors, that fishery administration must have an adequate biological basis, continued to receive due official recognition. His loss will be realized most fully by his immediate friends and colleagues, for most of his work was done under the cloak of official anonymity.

Until other claims on his time became more pressing, Green often attended the meetings of the International Council for the Exploration of the Sea, first as an expert on the staff of the British delegation and later as a delegate from the Irish Free State.

He was for many years an active member of the Council of the Dublin Zoological Gardens, and was elected a vice-president shortly before his death.

G. P. F.

WE regret to announce the death of Prof. Wladyslaw Grabski at Warsaw on March 1, after a long and painful illness. He had been rector and lecturer at the Polish Agricultural College and was an authority on the economics of agriculture. After the Great War and the liberation of Poland, Prof. Grabski became a prominent statesman, first as Minister of Agriculture and later as Finance Minister. During his period in office, he founded the State Agrarian Bank and also the Bank of Poland. In 1925, Prof. Grabski retired from political life and returned, as principal, to his old college.

WE regret to announce the following deaths:

Mr. Charles Benson, formerly deputy director of the Agricultural Department, Madras, known for his work on Indian cotton and tobacco, on March 5, aged eighty-two years.

Prof. Alfred Fischel, formerly professor of experimental embryology in the University of Vienna and editor of the *Zeitschrift für Wissenschaftliche Biologie*, aged sixty-nine years.

Prof. Friedrich von Krüger, for many years director of the Department of Physiological Chemistry in the Rostock Institute of Physiology, aged seventy-six years.

News and Views

Prof. I. M. Heilbron, F.R.S.

PROF. I. M. HEILBRON, whose appointment to the chair of organic chemistry in the University of London (Imperial College) has just been announced, is a man of many activities, that of a research director and teacher of organic chemistry being exceptionally prominent. Prior to the Great War, he held a lieutenancy in the A.S.C., 52nd Division, and proceeded to G.H.Q., Salonika in 1917. He was promoted lieutenant-colonel and assistant director of supplies, G.H.O., Salonika in 1918, and was given the D.S.O. and mentioned three times in despatches. It is, however, as a research chemist rather than as a soldier that he will be best recognized. His field, for many years past, has been in the sterol group and in matters generally relating to calciferol and the group which contains the important vitamin D; he has instituted a series of experiments on the synthesis of vitamin A and has progressed definitely towards a successful conclusion of this problem. He has also covered a wide field in other directions, particularly in connexion with the Algæ and carotenoid pigments. Since 1933, he has been able to give full scope to his genius and has made many important discoveries by the help of the large research school which he has gathered together. He was lecturer in the Royal Technical College, Glasgow, from 1919 until 1920; Heath Harrison professor of organic chemistry in the University of Liverpool in 1922–33, and thereafter professor of organic chemistry in the University of Manchester, succeeding Prof. A. Lapworth in the Sir Samuel Hoare chair in 1935.

Dr. J. S. Turner

DR. J. S. TURNER, senior demonstrator in botany in the University of Cambridge, has been appointed to the chair of botany in the University of Melbourne, in succession to the late Prof. A. J. Ewart. From the Sheffield Central Secondary School, Dr. Turner went up to Cambridge in 1927 as a scholar of Selwyn College, and after obtaining first classes in both parts of the Natural Sciences Tripos commenced research on plant respiration under Dr. F. F. Blackman in 1930. He was afterwards elected, successively, to the Frank Smart and Allen studentships in the University, and was awarded the Gedge prize for an essay on respiration in plants. He was appointed University demonstrator in 1934, and since 1936 has been in charge of the large practical classes for Part 1 of the Tripos in the Cambridge Botany School. His main research interest has been in plant physiology, especially in the relationship between respiration and fermentation in yeast and in the tissues of the higher plants. At present, he is engaged on a study of photosynthesis and respiration in aquatic plants. He is also much interested in ecology, and in association with Dr. H. Godwin has contributed substantially to the elucidation of the plant communities of Wicken Fen and the Norfolk Broads. In 1936 he organized a party of research workers to investigate the natural oakwoods of the Killarney district, and in other ways also he has been most successful in stimulating students to work in the field. At Melbourne, Dr. Turner will have a much wider sphere of work; with his enthusiasm as a teacher, and a happy combination of interest in laboratory and field experimentation, he assumes this important professorship with every augury of success.

Dr. Willis Jackson

DR. WILLIS JACKSON has been appointed to succeed Prof. Robert Beattie, who retires in September from the Edward Stocks Massey chair of electrotechnics in the University of Manchester, which he has occupied since 1912. Prof. Beattie has been associated with the University since 1896. Dr. Jackson was educated at Burnley Grammar School and the University of Manchester, where he graduated with first-class honours in 1925, and was the recipient of various prizes and scholarships. He has held the posts of lecturer in electrical engineering at Bradford Technical College and the Manchester College of Technology, and of lecturer in engineering science in the University of Oxford. Since 1936, he has been research engineer to the Metropolitan-Vickers Electrical Co., Ltd., and lecturer and tutor at the Board of Education Summer School for Engineering Teachers in Technical Colleges. His research work has been mainly devoted to high-frequency measurements and to the properties of insulating materials, and has appeared in numerous papers published in the *Proceedings of the Royal Society*, the *Journal of the Institution of Electrical Engineers*, the *Philosophical Magazine* and other journals.

Prof. Alexander Low

THE Court of the University of Aberdeen has accepted the resignation of Prof. Alexander Low, regius professor of anatomy in the University, to take effect on September 30. Prof. Low has occupied the chair since 1925, when he succeeded Prof. Robert Reid, whose assistant he had been for many years. Born in 1868, he was educated at the Aberdeen Grammar School and in the University of Aberdeen, afterwards studying at Freiburg, Vienna and Zurich. His association with Aberdeen as student and teacher covers a period of more than fifty-two years. In his professional studies, Prof. Low has specialized in anthropology and embryology, and has contributed a considerable number of papers to the journals of learned societies in anatomy, anthropology and embryology. He was one of the original members of the Aberdeen University Anthropological Society, to which British archæology is indebted for its contributions by excavation to early studies of the osteology of the 'beaker-folk'. For many years Prof. Low has been an active member of the anthropological section of the British Association.

Oxford's Programme of Development

A year ago the University of Oxford appealed to its friends for endowment on a scale appropriate to the part it is called upon to play in the world of learning to-day. The response was £426,000. This sum, with the new foundation of Nuffield College for the study of the social sciences, will provide for many of the needs which were mentioned in the appeal. It is strongly felt, however, that further development should take place, and for this a new appeal, which will remain open until July 31, has recently been made. The sum now asked for is £250,000. The most urgent need at the moment is the creation of a general research fund, both for the humanities and for the natural sciences. In the past ten years the number of research students at Oxford has doubled, and throughout the University there is a keen spirit of research. To endow a promising piece of research, whatever it may be, whenever an original line has been struck out, a research fund of £100,000 is regarded as essential. For the development of research in archæology it will be necessary to complete the extension of the Ashmolean Museum, and for this £15,000 will be required. It is felt also that as soon as possible the Departments of Physiology and Botany should have new laboratories. Towards the costs of these £60,000 and £40,000 are required. Lastly, another £35,000 is needed to complete and maintain the new physical chemistry laboratory that is to be erected. These sums make up the £250,000 which is being asked for.

Transatlantic Steam Navigation

In connexion with the centenary of the inauguration of regular steam passages between Great Britain and the United States by the four steamers *Sirius*, *Great Western*, *Royal William* and *Liverpool*, which all crossed and recrossed the Atlantic in 1838, a special exhibition has been arranged at the Science Museum to illustrate "One Hundred Years of Transatlantic Steam Navigation". The central feature of the exhibition is the magnificent model of the *Queen Mary*, the model being 22 ft. long. The gallery also contains models of the *Normandie*, the *Conte di Savoia* and other notable vessels of recent years. Of greater historic interest, however, are the newly made models of the *Sirius* and *Great Western*. The former ship was of only 703 tons gross and was never intended for work in the Atlantic, but she was the first steamer ever to cross the ocean from east to west using her engines as the main motive power. Her voyage began on April 4, when she left Cork, and ended on April 23, when she tied up in New York harbour. The *Great Western*, designed by the famous engineer Isambard Kingdom Brunel, was of 1,340 tons and it was she which demonstrated in unmistakable manner the possibilities of steam on the ocean. The original drawings of the ship are shown beside the model, and also various interesting documents. Other ships shown are the *Great Britain* and the *Great Eastern*, the *Britannia*, first of Cunard vessels, the *Scotia*, the last of the paddle vessels on the Atlantic, the *Servia*, the first steel liner, and the *Philadelphia*, the first large twin-screw ship on the Atlantic. The exhibition was opened on March 16, and will remain open until the middle of September. An illustrated handbook has been prepared by Mr. H. P. Spratt, the Museum officer who has arranged the exhibition.

Hadrian's Wall

Some major problems of the Roman Wall of Hadrian would appear to have been brought to a solution by recent excavations of the Durham University Excavation Committee, of which an account was given on March 11 before the Society for the Promotion of Roman Studies by Mr. I. A. Richmond of King's College, Newcastle-on-Tyne, co-director of the investigation with Mr. F. G. Simpson, of the Cumberland Excavation Committee. It is found that the lack of uniformity between the remains in different sectors of the Wall, which has been the main difficulty of the archæologist, is not due to haphazard work, but arises from deliberate changes in plan as the Wall was in course of erection, as well as to the differences in material available for building. From Newcastle to the Irthing the builders began with a wall of stone 10 ft. thick (afterwards reduced to 7½ ft. to expedite the work), erecting barracks for patrols in large courtyard gateways piercing the Wall at every mile, and hence called 'milecastles'. Over the north gate of each and at every 540 yards was a turret. This section of the Wall was then extended eastward to Wallsend; and a narrow stone wall built to the westward between milecastles 49 and 53; but in the main westward extension from the Irthing to Bowness-on-Solway, limestone for grout was lacking, and a turf wall took the place of the stone wall. It was supplied with stone turrets of distinctive type and milecastles of wood. This turf wall was replaced by a stone wall later in the century.

Tactical considerations now took the place of time and material, which had previously determined changes in plan. When the Wall was completed, eight forts were embodied in the line, holding either 500 cavalry or a nominal 1,000 infantry. Thus was formed a front line force capable of taking the offensive in overwhelming strength. It had been found that the Wall, designed originally as a patrol line, could be better used for concentrated garrisons, and thenceforward the emphasis was on forts rather than milecastles. Next in order comes the Vallum, the earthwork of which the ditch is the main feature, south of the Wall, the purpose of which has been the subject of much controversy. Mr. Richmond is of the opinion that it demarcates the military zone of the Wall and its dependent structures and also served as a barrier against southern marauders. Further excavation may show whether this view is to be regarded as final.

Toxicology of Narcotic Drugs

IN his presidential address before the Society of Public Analysts delivered on March 4, Dr. G. Roche Lynch discussed "The Toxicology of the Narcotic Drugs", embodying observations regarding the barbiturates, thio-barbiturates, straight-chain ureides and morphine, based on his own record of cases. He pointed out that the barbiturates, of which seventeen are now on the market, can be divided into two main groups, one of which produces light narcosis of long duration and the other deep narcosis of shorter duration. The individual barbiturates differ greatly in the rate at which they are destroyed in the body; some are destroyed so rapidly that it is rarely possible to recover more than minute quantities of them from urine or tissues. The extent of their use is illustrated by the fact that 18 million tablets of one of them, and that not the most common, are produced annually. The habit of taking them at night regularly is widespread, especially among women; but in keeping them within reach as a means of inducing sleep there is a danger that, after one or two tablets have been taken, a state of 'automatism' might supervene, in which a person, more or less unconsciously, might take a further number, with serious results. For purposes of treatment, the analyst should be able, by examination of urine, to ascertain within a quarter of an hour whether or not a barbiturate had been taken; but for purposes of evidence in court a complete identification with melting point determination is desirable.

Broadcasting Television

IN a discussion in the House of Commons on March 11 of the supplementary estimate for £360,000 for the B.B.C., Major Tryon made some very satisfactory remarks. He pointed out that in this year's report there were two entirely new features. First there was the expansion of television which accounted for an additional £295,000, and also about £15,000 proposed for broadcasting news in foreign languages. The latter sum was not included in the original estimate as it was not a part of the policy of the Government. He said that Great Britain was the first country in the world to have a public television service. It had been found by the Television Advisory Committee that further experiments must be made before new recommendations could be accepted for extension. That was a scientific inquiry, and he was sure that the House would like to pay tribute to the men of science who had made this wonderful discovery, and to the B.B.C. and its engineers for bringing it into working order. He also expressed the gratitude of the Government to the Television Advisory Committee, under the chairmanship of Lord Selsdon, who had been given great help in scientific matters by Sir Frank Smith. The additional sum required for television was provided simply. In the future 8 per cent of the licence revenue should go to the B.B.C. to help with the additional work. Television had only lately been started and the cost had been very heavy. If the service was to be efficient there must be a greater accommodation of studios, etc. The technical standards of television had been stabilized for three years, and that gave security to producers of sets and encouraged them to make more sets and more cheaply. This grant would foster the growth and development of an infant industry in which we were at present leading the world.

The British Broadcasting Corporation

THE eleventh annual report of the British Broadcasting Corporation, which covers the year ended December 31, 1937, refers to the completion of the first year of operation of the London Television Station, and the year's experience is regarded as having justified the confidence in the future of television which led to its establishment. Financial uncertainty which had complicated further plans was relieved towards the end of the year by the Treasury's acceptance of the view that the costs involved should be met by a grant from the balance of net licence revenue retained by the Treasury. The adoption of the Marconi-E.M.I. transmitting standards as a single system in February made it possible to widen the scope of television programmes during the year, notably in outside broadcasts. Reference is also made in the report to the work of the Talks Advisory Committee, to attempts to promote closer contact with listeners and various experiments in technique. The Engineering Section of the report refers to developments in Empire service and to the obstacle which lack of sufficient wave-lengths continues to present to the planning of extensions to the home service. Further progress in experimental studio design has been made, and improved methods were adopted in the acoustical treatment of studios under construction. The results of research on the performance of short-wave directional aerials were successfully applied in the design of the Empire station. The total income for the year amounted to £3,356,074, of which 85·67 per cent was derived from licences and 14·32 per cent from publications. Of this income, more than 51 per cent was expended on programmes and nearly 18 per cent of the remainder on engineering. £200,000 were transferred to capital account, an amount insufficient to cover the year's expenditure on fixed assets. The report stresses the impossibility of building up any reserve funds in liquid form, although this is most essential while income is still increasing.

Promotion of International Co-operation

THE annual Bulletin of League of Nations Teaching, just issued by the secretariat (No. 4, December 1937), deals with the teaching of the facts and principles of international co-operation, this subtitle indicating that its scope has been extended to cover a wider field than the activities of the League of Nations itself. The activities of the Advisory Committee on League of Nations Teaching continue to be reflected in the volume, which as in previous years gives publicity to those League activities likely to be of particular interest to educationists. The admirable series of articles in the present volume, particularly those on the role of intellectual co-operation in contemporary life and on the use of modern means of spreading information in the cause of peace, give it, however, strong claims on the attention of all who are studying or seeking to promote international co-operation and understanding. Moreover, the articles on the League of Nations at work, which covers the problem of raw materials and the League of Nations; the reform of the League; the League of Nations and International Hygiene; and Changing Aspects of Child Welfare, and on the International Labour Organisation, dealing particularly with the raising of the minimum age of admission to employment, represent concise and balanced surveys of the present situation of these problems which should be of real service to the speaker or general student. The reprints of broadcasts such as that on nutrition and the Singapore Health Bureau, of Sir Malcolm Delevigne on opium and drugs, and of Prof. Gilbert Murray on intellectual co-operation, provide other material of the same type.

Copper and Brass Welding in Germany

IN 1936, the Deutches Kupfer Institut of Berlin published a valuable pamphlet describing carefully the best methods of welding copper and brass. The Copper Development Association of London has now translated this into English. It is pointed out that there are certain differences between German and British welding practice, mainly associated with the general employment in Great Britain of deoxidized copper. But knowing the high standard of excellence which has been achieved in Germany, there is much of it which will be of value to British readers. The hand-made copper and bronze domestic vessels shown in the Berlin State Museum and dating back thousands of years prove that soldering and riveting were in common practice from very early times. In course of time, the necessity arose for a new and improved jointing technique which would produce smooth and strong joints and yet avoid the expense of riveting. This demand is universally met to-day by the adoption of welding. The development of copper welding has been much slower than that of steel, but the difficulties in the way have now been largely overcome, and welded copper appliances of the highest quality are now produced. Deoxidized coppers, which are extensively used in Great Britain, are not discussed in this pamphlet. The thermal conductivity of copper is about six times that of steel. Molten copper readily dissolves other metals and forms the basis of several important alloys. With zinc it produces brass and with tin bronze. The thermal conductivity of brass is two or three times that of steel, and only about one third that of copper. This feature is a decided advantage in welding. For this reason, brass requires a smaller flame for welding than copper. Although gas welding is the one most commonly used, new electrical methods are in process of development which will probably enable arc welding to be profitably employed.

The Clock of the Future

AT the British Horological Institute in London, on January 12, an interesting discussion was held on the respective merits of spring-wound and electric clocks. Mr. D. W. Barrett, of Smith's English Clocks, Ltd., began by pointing out that his firm has large investments in spring-driven clocks and its business was founded on them. He claimed to be impartial and he would not have taken up the electric type had he not been assured of its future. A spring-wound clock cannot be relied upon to give accurate time. It needs regular winding and its parts are delicate. The electric clock needs no attention and is robust. It is true that it stops when the current fails, but on the average this only happens once a year. There are areas where no break has been recorded for three years. In the United States, 66 per cent of the sales were of electric clocks. In Great Britain about 33 per cent of the money spent on clocks last year was for electric clocks of the synchronous type. When it is remembered that the spring-wound clock has been in existence for three hundred years whilst the electric clock has only been on the market for some seven years it will be seen that the latter is the more popular. There are about 45 million clocks in use in Great Britain, the bulk of them being spring-driven. There can be little doubt but that the electric clock will be the clock of the future. It is practically immune from the effects of heat and damp.

The Soviet Institute of Physical Problems

PART 3 of the *Physics Bulletin* of the Soviet Academy of Sciences for 1937 contains Dr. P. Kapitza's address to the Academy last March, which he devoted to an account of the new Institute founded by decree of December 1934. The building, which has taken a year longer to complete than was anticipated, is, although only 80 metres from Moscow tram lines, surrounded by gardens in which other institutes of the Academy are to be built. It nearly surrounds a quadrangle 40 m. × 25 m., with outer walls 63 m. × 50 m., the long side nearly north and south. The south-eastern corner is not built on, and gives access to the quadrangle. The main laboratories are on the ground floor, and provision for very sensitive apparatus is made in the basement. A first floor over the eastern block is occupied by the administrative department. By introducing a simplified system of book-keeping, Dr. Kapitza has reduced the five accountants originally thought necessary to one. The apparatus taken from Cambridge has been installed and is described. It includes the Metropolitan-Vickers alternator and the coil through which it is short-circuited to produce for 1/100 sec. an intense magnetic field, the hydrogen liquefier producing 7 litres per hour and the helium liquefier which first cools the gas to 65° absolute by means of liquid nitrogen, then to 10° abs. by adiabatic expansion and finally liquefies it by the Joule-Kelvin cooling. A new machine on this plan is now being constructed to work with a double cycle and deliver 6–8 litres per hour.

History of American Agricultural Research

A "History of Agricultural Experimentation in the United States, 1607–1925", by A. C. True, has just been issued as Miscellaneous Publication No. 251 by the United States Department of Agriculture, Washington, D.C. This is the third official monograph in a series intended to give a comprehensive summary of the history of agricultural education, extension and research in the United States, the two previously issued having dealt with agricultural instruction in schools and colleges, and the history of agricultural extension work respectively. The present volume naturally begins with the work of private individuals including some biographical information, and shows how they and organizations such as the geological surveys and the Patent Office, themselves little concerned with research, laid the foundations of public agencies for agricultural investigation. It will be noted with interest that the first governmental movement to help agriculture was made when George Washington was president, while Federal State aid for the agricultural experiment stations, founded by pioneers all over the country, was secured by Hatch in 1887 by the passage of an Act bearing his name. The rapid development of research from this period up to 1913, the effects of the Great War and the agricultural depression of 1921–25 are then described in detail. A bibliography of more than three hundred references is appended. These are limited to sources of information used in the text and to bibliographical sketches of some of the leading figures in the earlier periods of agricultural development in the United States.

Marine Fauna of the Isle of Man

THE publication of a new local fauna list is always an event of some interest, and it is of importance when it concerns such historic ground as that of the sea around the Isle of Man ("Marine Fauna of the Isle of Man". Compiled by Dr. Hilary B. Moore. Editor: Dr. R. J. Daniel, assisted by J. R. Bruce and Dr. M. W. Parke. University Press of Liverpool, 1937. 2*s*.). This up-to-date list of the marine animals found in that region is therefore to be warmly welcomed. Future visitors to the Biological Station at Port Erin will be grateful to Dr. Moore, a former member of its staff, for his work of compilation. He has been wise in following the same general plan as that of the well-known "Plymouth Marine Fauna", giving after each recorded name a reference to a good description, adding notes on the ecology, and breeding dates when known. There are three charts and a general introduction describing the most accessible and typical grounds. Dr. Moore and the editors have done their work well, while the printers have succeeded in producing well-balanced and attractive pages. As a work of reference, this list will be much used; to those studying the marine ecology of our islands it will be invaluable. We should like to suggest that in future editions a note be included as to the origin of the ancient drawing of a viking ship which so attractively adorns the cover.

The Film in Education

IN "The Film in Relation to the School Curriculum" (pp. 70; price 1*s*.) the Central Information Bureau for Educational Films, Ltd., has provided a useful reprint of a series of articles which appeared in *Film Progress* from July 1936 until July 1937. It deals with the teaching of geography, natural history, natural science and physical training. The advice given is in close accord with the Board of Education's "Suggestions for the Consideration of Teachers", "Suggestions on Health Education" and "Science in Senior Schools", long excerpts from which are reproduced. A report to the Manchester Education Committee on experimental film-teaching is quoted in support of the assertion that children are stimulated by this means to further effort in geography and nature-study. It is claimed that their interest and mental activity are so aroused as to lead them to seek out knowledge for themselves, their powers of observation and memory are increased and, in the case of geography lessons, the film tends to eliminate anti-foreign bias. Although some teachers prefer still pictures, it seems obvious that these cannot compete with such films as "The Life-Cycle of a Plant", "The Blowfly", "The Amœba" and physical training films.

Battersea Polytechnic

IN its recently published report for 1936–37 the Battersea Polytechnic directs attention to the increased volume and high standard of its research work. In the past, this has been pursued mainly in chemistry, physics and mathematics, but new facilities have made possible extended programmes in the Mechanical and Civil Engineering Department. In the Electrical Engineering Department, the demand for accommodation for research work could not be fully met. For researches in chemistry two Ph.D. and one M.Sc. were awarded by the University of London. Fifty-four other degrees of the University of London and thirty-four National Certificates in Engineering were obtained in addition to many other examination successes. An enumeration of positions obtained by Polytechnic students during the past thirteen years includes 1,218 domestic science inspectors, teachers, organizers and practitioners, 413 engineers, 413 health visitors, sanitary inspectors, nurses, etc., 233 chemists and 97 art practitioners. The general recognition of the enormous national importance of sound teaching in domestic science may be expected to lead to increased activity in this department of the Polytechnic.

The Plant Hormone Committee

As the outcome of a meeting held at the Royal Botanic Gardens, Kew, on November 6 (see NATURE, **141**, 88; 1938), a Committee, to be known as "The

Plant Hormone Committee" has been formed with the following membership: Mr. F. P. Knight (Knap Hill Nursery Co.), Dr. C. R. Metcalfe (Kew, convener and secretary), Mr. F. O. Mosley (Lowe and Shawyer, Ltd.), Prof. R. H. Stoughton (University of Reading), Mr. W. G. Templeman (Imperial Chemical Industries, Ltd.), and Dr. M. A. H. Tincker (Royal Horticultural Society). The terms of reference are "to consider the practical applications of 'phytohormones' in relation to plant cultivation". The committee is at present engaged in compiling a list of species of which cuttings cannot easily be struck even by experienced propagators, in the hope that by intensive experimentation, methods for propagating them successfully may be discovered. Further information about the committee may be obtained from the Secretary.

Announcements

PROF. A. KROGH, professor of animal physiology in the University of Copenhagen, and Prof. L. Lapicque, professor of general physiology in the Sorbonne, have been elected honorary members of the Physiological Society.

THE HON. SIR EVAN CHARTERIS, chairman of the Trustees of the National Portrait Gallery since 1928, chairman of the Tate Gallery Board since 1934, and Trustee of the National Gallery and Wallace Collection; Sir Francis Lewis Castle Floud, High Commissioner of the United Kingdom in Canada, Permanent Secretary, Ministry of Agriculture in 1920–27, chairman of the Board of Customs in 1927–30, and Permanent Secretary, Ministry of Labour in 1930–34; and Sir John Ledingham, director of the Lister Institute and member of the Medical Research Council, have been elected members of the Athenæum under the provisions of Rule II of the Club which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for their public services.

DR. BURGESS BARNETT, who was curator of reptiles at the London Zoological Gardens in 1932–37, and since then has been doing research on snake venom, has been appointed superintendent of the Zoological Gardens at Rangoon. Dr. Barnett will take up the new post in June.

PROF. H. ZEISS, of the University of Berlin Institute of Hygiene, has been elected president of the Berlin Microbiological Society in succession to Dr. J. Schumacher.

AT the annual general meeting of the Society of Public Analysts held on March 4, the following officers were elected: *President*, Prof. W. H. Roberts; *Vice-presidents*, B. S. Evans, J. R. Nicholls, W. H. Simmons, T. P. Hilditch (chairman, North of England Section), J. F. Tocher (chairman, Scottish Section); *Hon. treasurer*, E. B. Hughes; *Hon. secretary*, Lewis Eynon.

A VACATION Course on child psychology will be held on April 20–25 at Southlands Training College, Wimbledon Park Side, S.W. The course will be given in two concurrent sections: one for matrons of schools and one for medical officers and teachers. Further information can be obtained from the Secretary of the Child Guidance Council, Woburn House, Upper Woburn Place, London, W.C.1.

THE fifth European Congress of Mental Hygiene will be held at Munich on April 23–24, when the following subjects will be discussed: marriage prophylaxis and mental hygiene; prophylaxis of abuse of narcotics (alcohol, morphia, cocaine and hypnotics); and the importance of occupational therapy in physical and mental diseases.

THE League of Nations has sent a medical mission to the Far East to take measures to prevent or control the spread of epidemics. The mission is headed by Inspector-General Lasnet of the French Academy of Medicine; Dr. Hermann Mooser representing Germany and Dr. Robert Cecil Robertson representing Great Britain. The mission will first visit Hong-Kong and continue its work in south China.

ON the recommendation of their Science Scholarships Committee, the Commissioners of the Royal Commission for the Exhibition of 1851 have decided to increase from £250 to £275 a year the basic value of their overseas scholarships for scientific research, which are offered each year to students from Canada, Australia, New Zealand, South Africa, India and Ireland (Eire). The increase will take effect on April 1, 1938.

THE following awards of medals of the Institute of Patentees have recently been made: Grey-Wilson Memorial Gold Medal to Dr. S. C. Blacktin, for a dust and smoke meter (see NATURE, 140, 331, 582; 1937); Yorkshire Gold Medal to W. H. Siddle, for a wire-joining tool; Special Silver Medals to Mrs. F. Peace for a superhet washer, J. R. Churchill for a chair, W. McClelland for a balanced two-stroke engine, and to F. W. Mason for an automatic blind control.

THE following appointments and promotions have recently been made in the Colonial Service: B. W. H. Harding, inspector of mines, Kenya; W. G. R. Coates, engineer surveyor, Harbour Department, Hong-Kong; A. Gane, inspector of produce, Nigeria; P. H. Symons, assistant analyst, Medical Department, Hong-Kong; J. Pirie (agricultural superintendent, Gambia), agricultural officer, Nigeria; A. J. Wakefield (deputy director of agriculture), director of agriculture, Tanganyika; P. O. Wiehe (science master, Royal College), plant pathologist, Department of Agriculture, Mauritius; J. H. F. Sharkie (executive engineer, Public Works Department, Gold Coast), waterworks engineer, Public Works Department, Nigeria; J. Shelton (chemist), chief chemist, Institute for Medical Research, Malaya.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 518.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Radioactivity produced in Scandium by Fast Neutrons

ON irradiating scandium (^{45}Sc) with fast neutrons of energy $\leqslant 20 \times 10^6$ e.v., Pool, Cork and Thornton[1] observed two positron-emitting radioactive isotopes of scandium of half-lives 52 hours ('strong intensity') and 4 hours ('very strong intensity') respectively. With neutrons of $< 10 \times 10^6$ e.v., neither period could be observed. Previously Walke[2] had given the following assignment of radioactive isotopes of scandium: ^{44}Sc (52 hours), ^{43}Sc ($4 \cdot 0 \pm 0 \cdot 1$ hours), ^{42}Sc ($4 \cdot 1 \pm 0 \cdot 1$ hours). These he attributed to the reactions: $^{39}\text{K}(\alpha,n)^{42}\text{Sc}$, $^{41}\text{K}(\alpha,n)^{44}\text{Sc}$, $^{40}\text{Ca}(\alpha,p)^{43}\text{Sc}$, $^{42}\text{Ca}(d,n)^{43}\text{Sc}$ and $^{43}\text{Ca}(d,n)^{44}\text{Sc}$. Pool, Cork and Thornton suggested that the two periods which they observed were due to the formation of ^{44}Sc and ^{43}Sc resulting from the reactions

$$^{45}\text{Sc} + n = {}^{44}\text{Sc} + 2n - Q_1 \quad . \quad . \quad . \quad (1)$$

and

$$^{45}\text{Sc} + n = {}^{43}\text{Sc} + 3n - Q_2 \quad . \quad . \quad . \quad (2)$$

From the mass defect curve one can expect for the threshold energies the values $Q_1 = (10 \pm 2) \times 10^6$ e.v. and $Q_2 = (18 \pm 2) \times 10^6$ e.v. Energetically, therefore, both reactions might be possible, but the following discussion shows that it is difficult to understand why reaction (2) should take place more frequently than reaction (1).

Consider ^{45}Sc to be bombarded by homogeneous neutrons of energy E and denote by $P_1(E)$ and $P_2(E)$ the probabilities of reactions (1) and (2). P_2 will be zero for $E \leqslant Q_2$, and for $E > Q_2$ the 'evaporation' model indicates that it will increase rapidly with increasing E. It is not until $E - Q_2$ reaches values of the order of a few million electron volts that P_2 and P_1 will be of the same order. Furthermore, with a neutron source of the type used (a thick lithium target bombarded by deuterons of 6×10^6 e.v.), the neutrons of energy $E > Q_2$ will be very small in number compared with those of energy $E > Q_1$. Thus, the number of radioactive nuclei formed according to reaction (2) will be very small compared with the number formed according to (1).

We are therefore led to suspect that the two periods observed must be ascribed to ^{44}Sc and that this nucleus exists in two isomeric forms of half-lives 52 hours and $4 \cdot 1$ hours respectively. This would be consistent with the fact that both periods are obtained by bombarding potassium with α-particles, though previously[2] the $4 \cdot 1$-hr. period has been ascribed to ^{42}Sc. The 4-hr. period observed when calcium is bombarded with deuterons may be partly due to ^{44}Sc and partly to ^{43}Sc.

To test the hypothesis of isomerism we have bombarded scandium with neutrons of maximum energy 14×10^6 e.v. (obtained by bombarding lithium with 950 kv. deuterons) for which reaction (1) only, and not reaction (2), should be energetically possible. We have observed both the 52-hr. and 4-hr. periods with similar initial intensities (corrected for bombarding time). The particles emitted were found to be positrons. The isomerism of ^{44}Sc seems therefore established and the assignment of the radioactive isotopes of scandium should be as follows: ^{44}Sc (52-hr. and 4-hr.), ^{43}Sc (4-hr.). As to the radioactivity of ^{42}Sc, no evidence exists at present.

Gentner[3] has recently observed a 4-hr. period produced in scandium by γ-rays of 17×10^6 e.v. This he ascribes to ^{43}Sc formed in a $(\gamma, 2n)$ reaction. According to our results it appears that this activity should be attributed to ^{44}Sc formed in a (γ, n) reaction.

Deviations of Short Radio-Waves from the London-New York Great Circle Path

THE propagation of short radio-waves from England to New York has been found to involve many anomalous effects. Studies have been made of transmissions from Rugby, directed toward New York, and of broadcasts from Daventry using various transmitting arrays. Three multiple unit steerable antennæ (musas) located at the Holmdel, N.J. experimental receiving station of the Bell Telephone Laboratories have been used. One of these is the end-on musa described in a recent paper[1]. The other two are broadside musas steerable horizontally to permit explorations in azimuth. The British Broadcasting Corporation has kindly provided details of the transmitting antennæ in use during the various transmissions. These B.B.C. antennæ, together with the British Post Office transmitting antennæ in use on the London–New York radio telephone circuits, have provided simultaneous comparisons, which are, to a limited degree, representative of the effects of steerable transmitting directivity. Employment of the above facilities during the past eight months has disclosed the following characteristics:

(1) During 'all-daylight' path conditions, the usual multiplicity of waves distributed in or near the great circle plane, which constitutes normal propagation, has invariably been predominant. Neither ionosphere storms nor the catastrophic disturbances associated with short-period fade-outs seem to affect the mode of propagation.

(2) In contrast to (1), during periods of dark or partially illuminated path conditions, the great circle

plane no longer provides the sole transmission path. The extent to which other paths are involved varies greatly.

(*a*) Usually, transmission from mis-directed antennæ is accompanied by weak and scattered waves arriving off the great circle, in addition to normally propagated waves. Transmissions which emphasize radiation to the north especially exhibit such scatterings, arriving from north of the great circle with a considerable azimuthal spread. Acceptance of these scatterings by the receiving antenna results in rapid flutter fading.

(*b*) A considerable number of instances have been observed in which the ionosphere behaves as though it were warped, with resulting shifts of the wave path sometimes to the north and sometimes to the south with little regard to the transmitting directivity.

(*c*) Not uncommonly, the transmission medium displays more complex characteristics in which several azimuthal routes exist, the route selected by the waves depending upon the transmitting antenna. In these circumstances, transmitting antennæ directed, say 20 or 30 degrees off the great circle produce in the received waves, substantial deviations to the corresponding side of the great circle.

(*d*) On rare occasions, propagation during periods of dark, or partially dark, path conditions is entirely normal. That is, the waves travel in or near the great circle plane and are unaffected by the transmitting antenna directivity, except in amplitude.

When the transmitting antenna directivity is appropriate, the characteristic mentioned under (*c*) above often results in two paths sufficiently different in azimuth to be separable by one or the other of the broadside musas. The difference in the transmission time along such paths has sometimes been determinable by the method of audio delay equalization[1]. Such determinations are given in the following table :

Date 1937		E.S.T.	Station. Call	Station. Freq., mc.	Array Direction**	δ_1	δ_2	β_1	β_2	Delay Millisec.
May	28	7.54 p.m.	*GSB*	9·51	260°	11°	43°	2° S.	40° S.	1·50

Dec.	18	8.20 p.m.	*GSC*	9·58	294°			0°	30° S.	2·70
,,	21	7.00 p.m.	*GSC*	9·58	294°	13°	22°	5° S.	8° N.	0·54

E.S.T. = Eastern Standard Time.

δ_1 and δ_2 = 'vertical' angles measured with end-on musa.

β_1 and β_2 = horizontal angles measured with broadside musa, in degrees north (N.) or south (S.) of the great circle.

Delay is in all cases inserted in the β_1 path. It, therefore, is the shorter path in point of time.

* Rugby.

† Two synchronized transmitters.

** The direction to New York is 288° (measured clockwise from north).

Excepting the northern scatterings mentioned in (*a*), substantial deviations to the north have been rare, but large deviations to the south, such as the 30°–40° values in the table, have been found frequently. Southern deviations appear to be associated with ionosphere storms. In storms of moderate severity, southern deviations appear with noticeable consistency, even on Rugby transmission directed sharply to New York. In such circumstances, Daventry transmissions to the West Indies have been received much better with a low-gain broadside musa steered 60° south of the great circle, than a transmission in the same wave-band directed nearly to New York and received with a rhombic antenna directed towards England. In normal conditions, the superiority is reversed, of course.

It is known that during periods of disturbance the intense magnetic and auroral effects, which are normally found in the auroral zone, extend to more southern latitudes. It has been suggested by my colleague, Mr. W. M. Goodall, that the southern deviations in transmission might be connected with the southward expansion of the auroral zone during disturbed periods. For example, at such times as the zone extends southward to the London–New York great circle, normal transmission might experience great attenuation. Any southern route which may then exist, because of this zone or for other reasons, may then be superior to the great circle route.

Effect of Longitudinal Magnetic Field on the Refractive Index and Conductivity of Ionized Air

THE experimental study of an ionized gas in presence of the magnetic field has recently acquired considerable importance in connexion with the ionosphere. Notable investigations have been made by several authors[1,2,3,4,5] on the effect of the transverse magnetic field on the refractive index and conductivity of the ionized gas. Very few investigations have, however, been made in the case of the longitudinal magnetic field. Mitra and Ghosh[6] have recently observed the magnetic double refraction of ionized air in the presence of longitudinal magnetic field.

During the experimental study of the effect of longitudinal magnetic field on refractive index and conductivity of the ionized air, it was observed by us that in most cases the refractive index and conductivity of the so-called 'extraordinary' wave did not show any commonly assumed tendency to attain infinite values when the magnetic field was gradually increased. The plots of refractive index and conductivity against magnetic field yield curves as shown by the dotted *B* lines in Figs. 1 and 2 respectively. Such curves, however, can only be interpreted by the more complete equations for the refractive index and conductivity, and not by the generally used approximate equations which are obtained by neglecting the collisional frequency (ν) of the electrons. In the present note we point out that in cases where the refractive index and conductivity are measured as the strength of the magnetic field is increased, at a fixed frequency of the initial wave, the collisional frequency ν, however small, should not be neglected.

The complete equations used by us for calculating the square of the refractive index and conductivity (σ in E.S.U.) of an ionized gas in the presence of

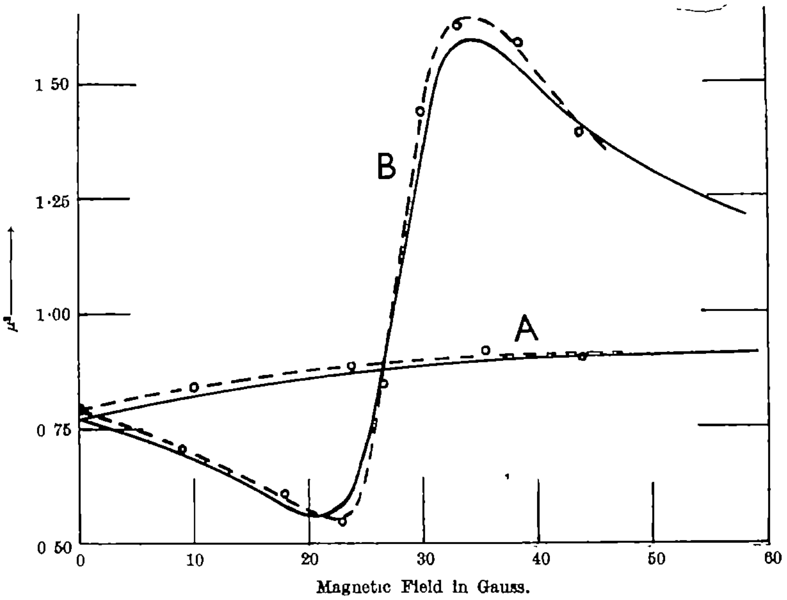

Fig. 1.

a longitudinal magnetic field may be shown to be,

$$\mu^2 = \tfrac{1}{2}\left[1 - \frac{(p \pm p_H)p_0^{\,2}}{p\{\nu^2 + (p \pm p_H)^2\}} + \sqrt{\frac{p^2\nu^2 + \{p_0^{\,2} - p(p \pm p_H)\}}{p^2\{\nu^2 + (p \pm p_H)^2\}}}\right] \quad . \; . \; . \quad (1)$$

$$\sigma = \frac{p_0^{\,2}\nu}{4\pi\,[\nu^2 + (p \pm p_H{}^2)]}\,; \quad . \; . \; . \; . \; . \quad (2)$$

where $p_H = \dfrac{He}{mc}$, H being the applied longitudinal magnetic field and the rest hold the usual meanings.

In the above equations the so-called 'ordinary' and 'extraordinary' waves are represented by the upper and lower signs of p_H respectively. It will be observed from the above equations that if ν be much smaller than p, in the case of ordinary wave it can be safely neglected for all values of p_H, since ν has to be compared with $p + p_H$. In the case of the extraordinary wave, however, ν cannot always be neglected even when it is considerably smaller than p, as ν has then to be compared with $p - p_H$, the value of which tends to become zero when p_H approaches p.

The arrangement of the apparatus was a modification of that adapted by Mitra and Ghosh[6]. As the intensity of the wave emerging from the discharge tube is considerably reduced due to absorption, a system consisting of a Hertzian dipole aerial was used in the output of an ultra-short wave oscillator for producing the impressed wave ($\lambda = 3{\cdot}71$ metres) and also at the input end of the Lecher wires. The conductivity was determined from the knowledge of leakance per unit length of the Lecher wires, which was measured by the method employed by one of us in connexion with the measurement of radiation resistance of transmission lines[7]. The refractive index was found by the usual method from the values of wave-lengths in air and in the ionized medium.

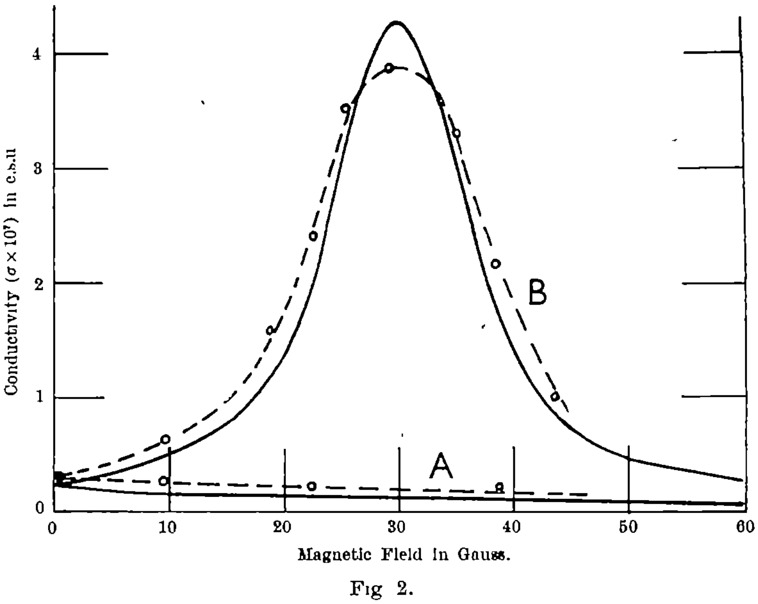

Fig 2.

Figs. 1 and 2, as already described, show the variations of the square of the refractive index and conductivity of ionized air when the magnetic field is gradually increased. The dotted curves are drawn from the experimentally observed values, and continuous ones from those calculated by equations (1) and (2). The curves for the ordinary and extraordinary waves are represented by A and B respectively. It will be observed from Fig. 2 that the maximum conductivity of the ionized air is obtained in the same region (near about $p = p_H$) where the irregularity appears in the values of refractive index, as shown in Fig. 1. From the above curves it will be seen that the inclusion of ν in equations (1) and (2) prevents the refractive index and conductivity from attaining infinite values.

X-Ray Study of Isoprene, Butadiene and Chloroprene at Low Temperature

In view of the considerable technical importance of isoprene, butadiene and chloroprene, as the hydrocarbons which on polymerization give natural and synthetic rubber, some interest is attached to the study of their structure. At normal temperatures they are in the liquid or gaseous state, and as it is possible to make exact X-ray structure measurements only in the solid state, the substances have been examined at liquid nitrogen and liquid oxygen temperatures, in a Debye-Scherrer camera, of radius 57 mm., employing a simple technique developed in the Davy Faraday Research Laboratory. Exposures of 30–90 minutes at 100 ma. were given.

Butadiene gives an extremely good X-ray diagram with about 35 measurable lines. Although the photograph provides adequate data as to crystal spacings, it has not been possible to identify the diagram with that of any of the crystal classes of high symmetry. It is probable that this substance is a crystal of a class which makes an analysis by the Debye-Scherrer method extremely difficult, if not impossible. The spacings calculated from the 10 strongest lines, using the Bragg relation, are given in the following table. The intensities are visual estimates.

Line	Butadiene intensity	Cu *K*α radiation θ°	*d* in A.
1	8	9·49	4 67
2	6	10·49	4 23
3	7	10·86	4·08
4	10	12 52	3·55
5	10	12 84	3·47
6	8	13·52	3·30
7	8	13·94	3 19
8	6	19 82	2 27
9	5	20 30	2 22
10	6	21·42	2 08

With long exposures chloroprene never gave diagrams showing more than three lines corresponding to spacings of 3·28, 2·57 and 2·32 A., and two diffuse 'liquid' rings the maxima of which corresponded to spacings of 11·78 and 3·24 A.

Isoprene (Schuckert) never seems to crystallize at all sharply, but gives a glassy mass. This is in accordance with the facts quoted by Beilstein. It is not therefore surprising that only 'liquid' rings appear on the X-ray diagrams. (This substance was also studied using a 35 kw. tube with a rotating iron anticathode. Even a long exposure with an intense X-ray beam failed to bring out any lines.) A photometer trace of one of the films indicated intensity maxima corresponding to spacings of 8·6, 2·4 and 2·0 A.

It is not proposed to continue this work for the present. The purpose of this note is simply to put on record the preliminary results which have been obtained.

I am indebted to Dr. W. J. S. Naunton of Imperial Chemical Industries, Ltd., for supplying me with the chloroprene and butadiene, and to Sir William Bragg and the Managers of the Royal Institution for the facilities they have afforded me.

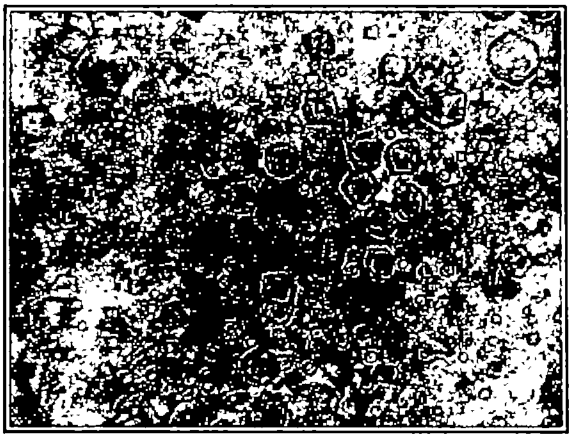
A Plant Virus Preparation in a Fully Crystalline State

Specific proteins, believed to be the viruses themselves, have been isolated from plants infected separately with each of seven viruses of the tobacco mosaic and potato virus 'X' groups[1–4]. Although these proteins have some properties in common with crystalline materials, and can be obtained in both solid and liquid anisotropic states, the solid preparations yet obtained lack the three dimensional regularity characteristic of true crystals. The particles of all these viruses are rod-shaped, and the connexion between this and the formation of fibres or pseudo-crystals has already been discussed[3,5].



Preparation of Bushy Stunt virus crystallized from ammonium sulphate solution. × 200.

From tomato plants infected with the virus causing bushy stunt[6], we have now isolated a specific protein which crystallizes in the form of rhombic dodecahedra. Solutions of this protein do not show anisotropy of flow, and the jelly formed by sedimenting the protein in a centrifugal field of 16,000 times gravity is not birefringent. As the crystals belong to the cubic system, they also are isotropic.

Infections (local lesions) of *Nicotiana glutinosa* can be obtained by rubbing the leaves with 1 c.c. of solutions containing 10^{-7} gm. of the protein, and 1 c.c. containing 10^{-6} gm. gives a visible precipitate with its antiserum. The activity of a preparation is unaffected by repeated recrystallizations or by sedimentation in a high-speed centrifuge.

After clarifying the infective sap by heating to 60° C. and centrifuging, the protein is isolated by repeated precipitations at room temperature with one quarter saturated ammonium sulphate solution. Impure preparations can also be fractionated by means of trypsin or a high-speed centrifuge. Crystallization is most readily effected by adding ammonium sulphate to a neutral solution at room temperature until the first sign of turbidity appears, immediately cooling to 0° C., and then slowly warming up to room temperature. The protein is much less soluble at room temperature than at 0° C., and as the clear fluid warms it becomes turbid and the protein crystallizes.

Analyses on dried preparations have given the following results: carbon 47, hydrogen 7·3, nitrogen 16, phosphorus 1·3 and carbohydrate 6 per cent.

This protein, like those we have isolated from plants infected with other viruses, appears to be a nucleoprotein, but it differs from them by having a rather higher nucleic acid content.

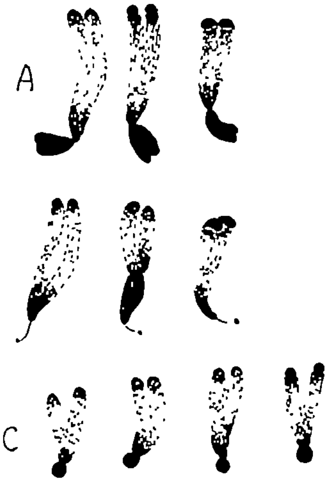
Heterochromatic (Inert) Regions in the Chromosomes of *Crepis capillaris*

GENETIC investigations on the inert regions in *Drosophila*[1,2] in connexion with the cytological studies on heterochromatin (inert chromatin) and the chromocentre[3-7] showed that the chromosomes have active (euchromatic) and inert (heterochromatic) segments; the proximal parts, near the centromeres, being the heterochromatic ones. These regions conjugate in the chromocentre in the salivary gland nuclei.

The data reported by Sturtevant[8] on the preferential segregation in triplo-IV female *Drosophila melanogaster* and those by Kikkawa[9], who studied haplo-IV *Drosophila ananasse*, indicating a probable conjugation between Y and IV chromosomes, suggested that non-homologous chromosomes most probably conjugate in the inert regions. More convincing evidence in this respect was supplied by Gershenson (in press) in studying the preferential segregation in triplo-IV flies having XY + fragmented X. Direct cytological evidence was supplied by Prokofieva[10], who showed that the second (inert) arm of IV chromosomes conjugate with the inert region of the left arm of the third chromosome.

A series of cytogenetic phenomena that occur in plants can be best interpreted if one assumes a conjugation between the inert regions of the non-homologous chromosomes. Heitz[11] and others showed that plant chromosomes (especially the sex chromosomes) have heterochromatic regions, but an exact analysis of the whole karyotypes, as in *Drosophila*[12], has not yet been carried out; therefore we have attempted to analyse the chromosomes of *Crepis capillaris*. This species has three distinct pairs of chromosomes: A, C, and D. Hæmatoxylin preparations with completely black chromosomes were slightly stained (fixation—Lewitzky-chromic acid-formalin). The proximal regions in each pair and the very distal ends remained darker, while the regions in between became lighter (see accompanying illustration). It should be noted here that the heterochromatic regions were not always exactly equal in length in all preparations. In some preparations the heterochromatin of the distal region (end) of C and D chromosomes were scarcely noticeable. We cannot decide yet whether in these particular cases it was completely lacking, or whether the chromosomes were highly stained. It is probable that the slight variations in length of the heterochromatic regions is due to the difference in density of euchromatin and heterochromatin. Perhaps such regions are partially active. In studying the karyotypes of *Secale* species[14] and *Nicotiana* species (Kostoff, unpublished), euchromatic and chromatic regions have been also found (compare chromosome 1 of *Secale Vavilovii*)[14].

The above data (also some others that cannot be mentioned here owing to limitation of space) in connexion with data reported by other investigators, a part of which is mentioned above, demand a revision of some cytogenetic conceptions and suggest new interpretations of known phenomena.



McClintock's data[15], for example, upon the non-homologous chromosome conjugations in *Zea* can be explained by assuming a conjugation between inert regions. 'Fold backs' of the univalents are results of attraction of inert regions. Her data as well as Avdulov's data[16] showed that in *Zea* even whole inert chromosomes occur. The terminal conjugation of the non-homologous chromosomes in haploids, as for example in *Triticum monococcum* ($n = 7$)[17,18], is obviously due to conjugation of distal heterochromatic regions of the non-homologous chromosomes. Numerous 'mutual' translocations in *Crepis* reported by many authors can be interpreted by the assumption of somatic interchange in conjugating inert regions. This concerns only the dynamics of the phenomenon. Stern[19] supplied convincing data for the occurrence of somatic crossing-over, and Peto[20] (in plant somatic tissue) and Levan[21] (in pollen) found direct cytological evidences.

Demerec and Hoover[22] found a viable deficiency. They wrote: "The deficiency 260–5 does not involve any of the visible extant loci. It takes a section of at least four bands at the tip end of the X chromosome. Flies homozygous for this deficiency are viable and fertile. They do not show any visible peculiarities." This deficiency is viable because it probably involves only the inert region. When one examines the drawings by Prokofieva[13] (Figs. 1, 4, 5 and 6) one sees that the very distal end of the X chromosome is inert.

In the light of these studies, it would be interesting to find out how much of the catenation in *Œnothera* is due to chromosome homology of the distal regions and how much to the conjugation between inert regions of the distal ends. *Œnothera* mutations, which are consequences of structural changes, might as well result from interchange in the inert regions of non-homologous chromosomes.

The probable rôle of the inert regions in interspecific hybridization and in evolution will be discussed elsewhere.

Occurrence of the Freshwater Medusa, *Craspedacusta sowerbii*, in Eastern Canada

SOME four years ago, we[1] had the pleasure of recording in NATURE the occurrence of the freshwater medusa, *Limnocnida rhodesiæ*, from new localities that increased its southern range in Africa. In the present communication we wish to give some details regarding the finding of the freshwater hydromedusa, *Craspedacusta sowerbii*, in the Province of Quebec, Canada, these being the first records of its occurrence in Canada, so far as can be ascertained.

Freshwater medusæ were first observed by Sowerby in June, 1880, in the *Victoria regia* tank in the Royal Botanic Gardens, Kew, and were described and named *Craspedacustes sowerbii* by Lankester[2] in the same year. The spelling of the name has since been modified to *Craspedacusta*. The first record of the hydroid or polyp phase was made by Parsons in 1884 from tanks in the Royal Botanic Gardens. Since then *Craspedacusta* has been notified from a number of places in the British Isles, France, Germany, Holland, Austria, Czechoslovakia, Poland and Russia. In Asia, *Craspedacusta* have been recorded from open waters in China and Japan. In the United States there are a number of records covering a large area of the country and forming a somewhat compact block of States. These States are Michigan, Illinois, Indiana, Ohio, Pennsylvania, New York, Missouri, Kentucky, Virginia, Washington, D.C., Oklahoma, Louisiana, Alabama and Georgia. The medusa has also been found in the Gatun Lake, Panama Canal Zone and in Brazil.

Two records, both of unexpected findings of *Craspedacusta*, are here presented for Canada. The first time that the medusa was obtained was on a hot afternoon in late June, 1934, when we were collecting aquatic fauna from the margins of Horseshoe Lake, which lies at the foot of Lake Manitou, a few miles from St. Agathe des Monts, Quebec Province. Horseshoe Lake is approximately at lat. 46° N., long. 74·25° W. It is a natural lake, about 800 yards long, 350 yards wide, with a maximum depth of 50 feet. Three mature medusæ were found among reeds at a shallow spot and several very small ones were recovered from the plankton then collected. Prolonged search and stirring of the water and silt with poles failed to reveal more medusæ, nor were any hydroid stages found. The mature medusæ were all females and were 10–12 mm. in diameter. There were numerous Protozoa, Entomostraca and tadpoles present, so that abundance of food for the medusæ was available. Subsequent searches by friends and ourselves at Horseshoe Lake have been negative for *Craspedacusta*.

The second habitat for the medusa in Canada is from a locality between Cantik, Quebec Province, and Rouse's Point, New York State, United States, these places being the Customs and Immigration Stations of Canada and the United States respectively, on either side of the international frontier. A naturalist friend sent us a bottle containing seventeen medusæ, which he had found accidentally when searching for a lost ball in September 1938. Rouse's Point is in lat. 44·58° N., long. 73·25° W., according to several gazetteers. The exact site of collection cannot be given, but the collector was very definite that the medusæ were found well on the Canadian side of the boundary, in a hollow containing about two feet of water, with abundance of grass and rushes. The weather was hot at the time of collection and the water was warm. Four days later the area was visited again, but no medusæ were found. The medusæ collected earlier were preserved in formalin and were in good condition when we received them. On examination, all of them were found to be females. They varied from 7 mm. to 15 mm. in diameter, most of them being between 10 mm. and 11 mm. in diameter.

Mature *Craspedacusta* from both localities were typical specimens. The umbrella was not very thick, the mesoglœa being up to 1 mm. thick in those measured. The manubrium was quadrangular and there were four lip-like projections around the relatively small mouth. The four radial canals were well-marked, arising from the angles of the manubrium and passing to the rather voluminous peripheral ring canal. The nettle-ring was distinct and somewhat smooth. The contractile tentacles varied in number with the age of the medusa. Thus, a medusa of 11 mm. diameter had 218 tentacles, the per-radials being 6 mm. long, while another medusa of 12 mm. diameter had about 360 tentacles. Counting the smaller tentacles was difficult. In some of the larger medusæ the arrangement of the tentacles in seven series, as postulated by some European workers, was discernible, while in medium-sized but sexually mature medusæ only four rows could be differentiated. In the smallest medusæ from Horseshoe Lake four per-radial and four inter-radial tentacles were present. These small forms were 0·5–2·5 mm. in diameter. In the mature medusæ very numerous coiled nematocysts with much coiled filaments occurred on the tentacles. Statocysts were embedded in the velum, with their broad bases towards the nettle ring. They were refractile and had short stems. The number of statocysts in the larger medusæ varied, there being roughly about one statocyst to every two or three tentacles. The mature medusæ were all females, the gonads appearing as elongate pouches or flaps on the radial canals and containing well-formed ova.

These Canadian *Craspedacusta* have been compared with specimens of *Craspedacusta sowerbii*, which Dr. Dejdar[3] kindly sent us from Prague in exchange for *Limnocnida rhodesiæ*, and with *Craspedacusta sowerbii* (or *rileyi*) given us by colleagues in the United States. Morphologically the Canadian medusæ are like both the European and the American forms, and we are inclined to the view of Dejdar and of some American workers that *C. sowerbii* and *C. rileyi* are either the same organism or are but local varieties thereof. *Craspedacusta sowerbii*, then, would be the correct name and the species name *rileyi* would fall into synonymy. The Canadian freshwater medusa would appear to be *Craspedacusta sowerbii*.

From the literature available, it is found that more than thirty sites of occurrence of *Craspedacusta* have been recorded in the United States since the organism was first definitely described by Hargitt[4] in 1907 from Washington, D.C. Budding of minute medusæ from *Microhydra ryderi* had been previously reported by Potts in 1895. The medusa has been found in rivers, lakes, ponds (natural and artificial), quarry pits, reservoirs, filter beds and aquaria. In Canada the habitats of the medusæ were a natural lake and standing water in a grassy hollow, virtually the condition of a temporary pond.

The Canadian locality at Horseshoe Lake, lat. 46° N., at present appears to be the most northerly record of *Craspedacusta* for the American continent, and between Cantik and Rouse's Point, long. 73·25° E., the most easterly record. The most northerly record for the United States appears to be that of Woodhead[5] for Ann Arbor, Michigan, lat. 42·15° N. and the most southerly one Monroe, Louisiana, lat. 32·03° N., given by Viosca and Burkenroad[6].

Our experience of the behaviour of *Craspedacusta sowerbii* in Canada agrees with those of other workers on the organism. It is noted for its sudden and erratic appearance and disappearance in a locality and for the difficulty of finding the hydroid form. Also, often the medusæ from one locality are all of the same sex. Both the type of freshwater habitat and the time of appearance of the medusæ are variable and, in localities where they were found on one occasion, they have not been found again despite searches extending over several years.

A Whale Shark Rammed by a Vessel off the Pacific Coast of Western Panama

ON May 30, 1932, a whale shark was caught on the bow of the United Fruit Company's steamer *Talamanca* in lat. 8° 14′ N. and long. 82° 46′ W., in the Pacific near Burica Point on the western boundary of Panama. This information was communicated to the U.S. Hydrographic Office by the second officer of the ship (whose name was not given), and was passed on to me by Admiral W. R. Gherardi, hydrographer. Accompanying the account was a splendid photograph showing a whale shark hung on the stem of the vessel.

In my search for exact data on this occurrence, I was handicapped in not knowing the name of the officer who had made the report. For the search I had only the name of the ship and the date. But after prolonged correspondence with the Hydrographic Office and with the United Fruit Co., I finally located the man who observed the occurrence, the second officer of the *Talamanca*, who had been transferred to another vessel and, on another run, had been far away. However, presently there came to my office in the Museum Mr. Paul R. Jones, to whose courtesy I am indebted for the essential facts of this interesting occurrence.

The steamer was proceeding from Panama to Puerto Armuelles on May 30, 1932. The sea was smooth, and fish and porpoises were feeding at the surface. Other porpoises were tumbling in front of the vessel, while a whale shark was lying at the surface to one side of the vessel. Suddenly, for some unknown reason, the great fish swam directly across the vessel's course and was caught on her bow. Since port was only twenty-five miles away, the vessel did not stop to get rid of the fish. In port the fish was dislodged and Mr. Jones noted that it was spotted like a leopard and that it was between 15 ft. and 18 ft. long. Impaled on the bow, the head and shoulder parts were on the left and the greater portion—about 15 ft. long—swung to the right. Thus caught, and being rather small for a *Rhineodon* (which has been measured up to 45 ft.), the shark did not impede the movement of the vessel as it would have done had it been struck nearer the middle.

In addition to being an interesting and unusual method of capturing a whale shark, Mr. Jones's data established a new faunal locality for *Rhineodon typus*. It has been recorded from Cape San Lucas in Lower California, from Guaymas in the Gulf, from Acapulco on the southern Mexican coast, in Panama Bay, at the Galapagos, and off Callao, Peru. I have elsewhere[1] given the geographical distribution and the history of every known specimen of *Rhineodon* up to December 31, 1934. The region of greatest abundance is in southern Philippine waters, and I assigned the Cape San Lucas region and the waters south of it as a second centre of concentration. This new record adds strength to that suggestion.

Dipole Moment of Pyridine

PREVIOUS workers have obtained values for the dipole moment of pyridine in benzene varying from 2·11 to 2·26 units. We have measured this moment in six solvents at 20°, using carefully purified pyridine having the following physical constants: density $d_{20}^{4} = 0{\cdot}98272$; b.p. 115·2–115·3°/760 mm.; refractive index $n_{D}^{20} = 1{\cdot}50920$; $P_E = 24{\cdot}02$ c.c. The results for tho polarization and moment are as follows:

Solvent	Dielectric constant	P_{20° c.c.	Dipole moment μ
Hexane	1·899	127 7	2 21
Cyclohexane	2 018	126·5	2·20
Carbon tetrachloride	2 234	139·3	2·33
Benzene	2 279	132·6	2·26
Toluene	2 380	131 0	2 25
Carbon disulphide	2 638	117 8	2 10

The polarization in hexane, cyclohexane and carbon tetrachloride was almost independent of concentration and was greatest in the solvent of lowest dielectric constant. These results also show similarity with those for nitrobenzene in hexane ($\mu = 4{\cdot}03$) and carbon disulphide ($\mu = 3{\cdot}70$)[1], although the difference in moments in hexane and carbon disulphide is rather less for pyridine than would be expected from a consideration of the moments of nitrobenzene in the same solvents. This result would be explained if, as is probable, the pyridine molecule is more spherical than that of nitrobenzene. This would be expected from a consideration of the Kerr constants for pyridine and nitrobenzene, which are:

	Temp °C	$K \times 10^{15}$	$K_1 \times 10^{15}$	$K_2 \times 10^{15}$
Pyridine	146·3	25·7	4·1	21·6
Nitrobenzene	235·5	146·0	7·0	139·0

where K_1 is the anisotropic constant and K_2 the dipole constant at 760 mm. and 546 $\mu\mu$.

The polarization of pyridine in benzene and toluene was, however, found to decrease considerably with increasing concentration, this indicating a larger degree of dipole association in these two solvents than in hexane, cyclohexane and carbon disulphide. The higher value of the moment of pyridine in benzene and toluene may be due to association of pyridine molecules with the molecules of the solvent.

The high moment of pyridine in carbon tetrachloride is probably due to the formation of a complex in solution. This would be expected, since complex formation has been observed in the case of quinoline and carbon tetrachloride[2].

The work is being extended to quinoline and isoquinoline and the results will be published in detail in due course.

Anaphylactic Sensitivity Produced by a Chemical Substance

THE phenomena of anaphylactic supersensitivity has been ascribed hitherto to a specific property of natural albumins, and the facts found so far were always explained by the supposition that albumin played an important part in anaphylactic reactions.

It is true that in some cases the *shock* could be reproduced by substances which are practically free from albumins, but these substances are of unknown constitution and are derived from different micro-organisms, such as pneumococci, *Achorion Quinckeanum*, etc. These natural substances are regarded as carbohydrates.

We have now reproduced the anaphylactic sensitization as well as anaphylactic shock by using a compound of known chemical constitution. It is absolutely free from albuminous substances and melts at 184–185°.

This substance, which corresponds to a full antigen, has the following constitution:

$$\mathrm{CH_3(CH_2)_7{-}CH{=}CH{-}(CH_2)_7{-}CO{-}N(CH_3){-}CH_2{-}CH_2{-}SO_3{-}Na}$$

Oleyl-(*n*)-methyl-taurin.

These facts will be discussed in the paper to appear in the *Helvetica chemica Acta*.

The Advancement of Science and Society

MEMBERS of the American Association for the Advancement of Science have read with much interest the comments on their resolution on international co-operation of scientists which appeared in NATURE of January 22, p. 150. As gratifying as these comments are, in one respect they differ somewhat from the spirit of the resolution.

Since I wrote the resolution and am suggesting to the Executive Committee that it extend formal invitations for an international conference of representatives of scientific societies to be held in London this coming summer, I should like the privilege of explaining the spirit of the resolution, which I believe represents the present sentiment of a large majority of the members of the American Association. By frank expressions of opinions well in advance of the contemplated conference we shall be able to make progress towards mutual understandings of possible slightly different points of view and thus prepare the way for constructive action at the conference, if it should be held.

The resolution passed by the American Association on December 30 was published in the article in NATURE referred to above.

The preamble to the resolution consists of two distinct parts, the first of which acknowledges the profound effects of science upon society and thereby admits a heavy responsibility of men of science to their fellow men. The second part expresses the pure objectivity of science and states conditions only under which it can flourish permanently. Differing from the 1933 resolution of the American Association and from possible interpretations of the comments in NATURE, this preamble is in no degree political or national. There is in it absolutely no note of criticism of Governments or of social orders, for condemnatory words seldom lead to harmony and co-operation.

The resolution itself also consists of two parts, the first of which pertains only to the American Association. It expresses directly only what has long been a distinct policy of the Association. For example, the Section on Medical Sciences is now organizing the tenth of its symposia, participated in by leading American specialists, on subjects (in this case mental health) of wide public interest and importance. Another section has held important symposia on various aspects of conservation of natural resources, while still another has made plans for five symposia on the general title "Science and Society", of which one has been held.

The second part of the resolution relates entirely to international co-operation of men of science. The invitation to co-operation is not dependent on racial, political or theological qualifications; it is open to every organization in the world the purposes of which are to spread the benefits of science to all mankind.

This sadly disordered world needs some new objective upon which it can focus its attention, some new course of procedure which it will ardently follow. It is possible that men of science can set up such an objective and gradually work out practicable methods for attaining it. Certainly, of all the conclusions that men hold, those of scientists are most easily verifiable and the methods of scientists are most easily evaluated and standardized. The verifiable nature of much of the work of scientific workers and the relative freedom of their conclusions from emotions and prejudices insures for them from the beginning a considerable amount of common ground. Possibly this common ground can be gradually enlarged until it will form a substantial basis for the general progress of civilization. Is it too much to hope that international problems of health, for example, that have been precipitated by the applications of science should be attacked and solved by scientists ? Would not the altruistic spirit exhibited by science meet a compelling response in the general conscience of mankind ?

Without anticipating what recommendations the American Association may desire to make respecting the purposes of the proposed conference, and not wishing to do more here than to open the question for preliminary discussions, I suggest three things that might be considered and attempted: (1) The formulation of a set of fundamental scientific principles of an ethical nature on which unanimous agreement of the delegates can be reached. (2) The formulation of the maximum number of inviolable methods of international intercourse and co-operation among scientists on which the delegates can unanimously agree. (3) The planning of the necessary machinery for making effective and enlarging the agreements reached in (1) and (2).

Points from Foregoing Letters

WHEN scandium (^{45}Sc) is bombarded by fast neutrons, two periods, of 52 hours and 4 hours respectively, are observed. These periods have been previously attributed to the formation of ^{44}Sc and ^{43}Sc. It is shown by W. E. Burcham, M. Goldhaber and R. D. Hill that both periods are due to ^{44}Sc, which nucleus, therefore, exists in two isomeric forms.

C. B. Feldman's letter reports investigations of London–New York short wave radio circuits in which newly developed steerable antennæ are used as direction finders. It is stated that, after darkness has begun to fall on the great circle and during the dark period, wide deviations from the great circle sometimes occur in transmission. They are principally southern deviations and seem to be related to ionosphere storms.

Graphs showing the effect of a longitudinal magnetic field upon the refractive index and the conductivity of an ionized gas, are submitted by Dr. S. S. Banerjee and B. N. Singh. The experimental findings agree with the theoretical values calculated by means of new equations in which the collisional frequency is taken into consideration in order to prevent the refractive index and the conductivity from attaining infinite values.

Some results of an X-ray study of the structure of isoprene, butadiene and chloroprene (from which synthetic rubber is produced) are communicated by Dr. C. J. Birkett Clews. At the temperature of liquid air, butadiene gave a good X-ray diagram with about 35 measurable lines which, however, could not be identified with those of any crystal classes of high symmetry; chloroprene gave diagrams with three lines and two diffuse 'liquid' rings; while the results obtained with isoprene indicated a glassy structure.

A virus which crystallizes in the form of rhombic dodecahedra has been isolated by F. C. Bawden and N. W. Pirie from tomato plants infected with the virus which causes bushy stunt. The crystalline substance is apparently a nucleoprotein with high nucleic acid content. It produces infections (local lesions) in *Nicotiana glutinosa* in dilutions of one part in ten millions, and one part per million gives a visible precipitate with its antiserum.

Diagrams of the chromosome pairs in *Crepis capillaris* are given by Prof. D. Kostoff and N. Arutiunian to show the presence of active (euchromatic) and inert (heterochromatic) regions. The authors believe that many cytogenetic phenomena (such as the 'mutual' translocations in *Crepis*) can be best explained by assuming a conjugation between the inert regions of the non-homologous chromosomes. The inert regions may also play a part in interspecific hybridization.

A communication from the late Prof. H. B. Fantham and Mrs. Fantham (Dr. Annie Porter) records the occurrence of the females and young of the freshwater medusa, *Craspedacusta sowerbii*, in Canada at two localities in Quebec Province. The finding of *C. sowerbii* at Horseshoe Lake, Quebec, lat. 46° N., extends the known range of the medusa almost 4° to the north. A habitat approximating to a temporary pond between Cantik, Quebec and Rouse's Point, New York State, long. 73·25° E., is the most easterly record for North America.

The dipole moment of pyridine in six solvents has been measured by B. A. Middleton and Prof. J. R. Partington, and has been found to vary from 2·10 to 2·33. The results indicate that the pyridine molecule is more spherical than that of nitrobenzene and that in benzene and toluene association with solvent molecules may take place. In carbon tetrachloride a complex is probably formed.

Research Items

Microlithic Industries of India

A LIST of microlithic sites in India compiled by Col. D. H. Gordon in *Man* of February shows that so far as our knowledge extends at the moment, these industries extend from Sind on the west to Orissa on the east, and from Mirzapur in the north to Cuddapah (Madras) in the south. It is unlikely that these industries are all contemporary or even in some cases connected in any way. The Indus valley ribbon flake and large core industry is quite separate, and the thick coarse flakes of Bolari Hill, Kotri, etc. (Sind), are of a type not found elsewhere. The area of Mahadeo Hills and Jubbulpore presents an industry homogeneous in type and material. That covered by the Franks collection in the British Museum, Bundlekund and Baghelkund, almost certainly contains an extension of the same culture. The shelters at Singhanpur and Kabra Pahar in Raigarh State also appear to be associated with an industry very similar in type and material. The central Indian industry displays a wide range of types, including crescents, triangles, trapezes (very rare), crescentic blades, straight blades, disk-scrapers and end-scrapers, worked points, borers and cores. Unworked blades and chips are in abundance in localities that were factory sites. One true arrow-head can be claimed; other points have been found with signs of having been worked to form a tang. Association with rock-shelters containing paintings, none likely to antedate 500 B.C., and with pottery in the floors suggests that in these remote regions a microlithic culture may have persisted into the early centuries of our own era. The Pachmari Plateau (Central Provinces) has in addition to rock shelters three factory sites at Tamia. The industry at Singhanpur is of the same microlithic type, the flakes being scattered on a large area to the north of the village. The stone workers lived on the present village site, which probably has been occupied ever since. In northern Hyderabad, the site at Ellora is notable for its proximity to the famous caves. Microliths from Bombay are scanty, while the Punjab has produced none. The microlithic nature of the industry is attributed to the small size of the stone available and renders equation with Western industries unsafe.

Co-operation of Social Groups

THE co-operation of social groups is the subject of a recent article by Prof. F. C. Bartlett (*Occupational Psychology*, 12, No. 1). Few problems of contemporary social life attract more discussion than those connected with the co-operation of differently organized social groups. The impossibility of any effective social group living its life alone is a matter of daily experience, and yet while the need for co-operation is recognized as a necessity for modern groups, actually little is known of the conditions and circumstances on which such co-operation may depend. Prof. Bartlett suggests a study of smaller social groups than the nation, and makes an experimental beginning by collecting accounts of concrete situations, all within the experience of his subjects and all involving a situation between rival groups, forced by circumstances to consider co-operation and finding it necessary to begin. The subjects of the experiment were asked to assume the correctness of the descriptions and to give reasoned judgments as to whether co-operation would break up or develop. The tentative results showed that an ordinary person could give a considered opinion as to the probable chances of the co-operation failing or succeeding; that there was considerable agreement regarding the primary bases of social concord and discord; and that ideas about the leading conditions of social co-operation and discord may vary from one section to another even of the same general community. The writer hopes that investigators will study social harmony and discord, so that it may be possible to understand and control the conditions.

Spread of Grey Squirrel in Britain

CONTINUING his former work, A. D. Middleton, with the help of B. T. Parsons, has summarized the extension of range of the grey squirrel (*Sciurus carolinensis*) in 1937. In many areas on the margins of its former colonies this introduced squirrel continues to spread (*J. Animal Ecology*, 6, 286; 1937). In its central region in England it has pushed farther afield, mainly in the marginal zone from Lincolnshire to Monmouth. It now occurs on the Somerset side of the Avon near Bristol, has increased near Exeter, and there is a notable westward spread to Ashburton. In Yorkshire, as in Essex, there has been less movement, but the whole of North Yorkshire, with Darlington and South Durham, most of West Yorkshire as far as the Pennines, and parts of East Yorkshire are now occupied. In the Cheshire and North Wales district extension northwards has occurred to near Mold and also into the Wirral. In Scotland little change is reported apart from a slight spread to the east, in the 'kingdom' of Fife. Since the grey squirrel has shown itself to be destructive to woodlands, its further and steady extension of range is a matter of some concern.

Control of the Red Spider Mite

THE Lyth Valley, in southern Westmorland, is the site of a localized damson-growing area. A variety known by the name of the county is the chief kind which has been planted, and it is unfortunately very prone to the attacks of the red spider mite *Oligonychus ulmi*. R. A. Harper Gray and H. E. Brooks have investigated methods of control of the pest by spraying (*J. Roy. Hort. Soc.*, 63, Pt. 2, 77, Feb. 1938). Five winter washes gave less control than summer sprays, but a 10 per cent emulsion of tar oil and petroleum was the most satisfactory of those applied in the dormant period. Successful fluids for summer application were refined white oil emulsion, lime-sulphur, and a 2 per cent petroleum wash. In spite of the increased efficacy of the summer treatment, however, control by the winter emulsion is likely to prove a more practicable means of control, since its application would not compete with other pressing work in summer.

Protein Breakdown in Germinating Sweet Peas

CARBOHYDRATES form the chief food store in the seeds of the sweet-pea (*Lathyrus odoratus*), but proteins also are an important factor. In his investigations into the protein breakdown in sweet-pea seeds, W. E. Isaac has shown that these seeds have a protein content amounting to 29·13 per cent, or 33·6 per cent on a dry weight basis (*Ann. Bot.*, New Series, 2, No. 5, January 1938). It was found that during the experimental period of ten days germination about one third of the protein content was broken down. During the first two days, breakdown was slow; until the sixth day it was more intense, and thence until the tenth day it continued at a uniform, though reduced, rate. These and other results are discussed with reference to the utilization of the energy released by this breakdown.

Climate of North East Land

FROM an account of the meteorological observations of the Oxford University Expedition to North East Land in 1935–36 by Mr. R. A. Hamilton, which was read before the Royal Meteorological Society on February 16, an impression can be obtained of the climate of that remote Arctic island beyond Spitsbergen, which is about equal in size to Wales and lies in about latitude 80° N. The observations cover the period August 24, 1935–August 12, 1936, which is much longer than any previous period of observation. The author states that arctic tradition credits North East Land with very severe and cold winters and with almost continuous gales of between 40 and 100 miles per hour. Such were not the characteristics of the climate during the period under review, but there is reason for believing that the expedition chanced upon an unusually mild winter. A number of observing stations were set up, one of which, on Mount Toil, was 2,060 feet above mean sea-level. A striking feature of the climate at the main base, near the entrance to Brandy Bay, was the concentration of winds into two opposing directions, south-east and north-west, and there was evidence that this peculiarity was shared by an extensive area including most of the Bay. Temperature at all stations was liable to the sudden changes so common in many parts of the Arctic, in winter and spring, variations of about 30° F. in one day being observed. A big fall of pressure generally brought strong winds or gales from south-east and a rise of temperature, followed by a big fall of temperature with increasing pressure and a north-west wind. At the main base the extreme range of temperature was from – 26° F. on an occasion in March to 52° F. in June and 51° F. late in August, and the high-level stations on the permanent ice cap on West Ice, although much colder, especially in summer, showed nothing below – 26° F. Temperatures above 15° F. were recorded in every month. All through the summer, with very few breaks, the ice-cap was shrouded by mist, which generally began at about a height of 300 ft. on the hills around the base. The observations definitely disproved the tradition of continual violent gales; some months in the winter half of the year, indeed, passed without any gales.

Hydrides of Boron

THE structure of B_2H_6 has been represented by Wiberg as $H^+(H_2B{=}BH_2)H^+$ and this 'acidic' representation has been supported by the formation of a supposed diammoniate, $B_2H_6.2NH_3$. H. I. Schlesinger and A. B. Burg (*J. Amer. Chem. Soc.*, 60, 290; 1938), who found that by interaction of this compound with sodium in liquid ammonia only one equivalent of hydrogen was liberated per mol of diborane, forming a stable salt NaB_2H_8N, and that on allowing the temperature to rise more hydrogen is evolved, but never more than 1·4 equivalents, now describe experiments in which it is shown that borine trimethylamine does not react with sodium. They propose to regard the so-called diammoniate as a mono-ammonium salt in which an atom of nitrogen is interposed in the boron chain, B—N—B. The evidence is indirect. The production of one equivalent of hydrogen by reaction with sodium is explained by assuming the composition $NH_4{}^+[H_3B.NH_2.BH_3]^-$. The slow reaction with further evolution of hydrogen is explained if ammonia removes a BH_3 group by a reversible reaction with production of $NH_4BH_3NH_2$. This is supported by the reaction of $(CH_3)_3N$ with $B_2H_6.2NH_3$ to give borine trimethylamine. The reaction of the new compound $(CH_3)_2OBH_3$ with ammonia and sodium produces the salt $NaBH_3NH_2$, which strongly absorbs B_2H_6; this justifies the assumption that the negative ion of the above structure is easily formed by addition of BH_3 to $BH_3NH_2{}^-$ and is capable of stable existence. The new compound B_2H_7N, having the skeleton B—N—B, is easily prepared from $B_2H_6.2NH_3$.

Crystal Chemistry

A VALUABLE review of progress made in the crystal chemistry of non-metallic inorganic substances during the years 1927–36 by F. Machatschki appears in *Die Naturwissenschaften* (26, 67, 86; 1938). The review deals first with elements, and then with compounds, particularly silicates, borates and complex compounds. There are plentiful references to the literature.

The Lightning Discharge

B. F. J. SCHONLAND (*Proc. Roy. Soc.*, A, 164, 132; 1938) has now given some conclusions on the mechanism of the lightning flash, resulting from his study of the flash by moving-image cameras. The discharge, in all the cases observed, makes the cloud a cathode, and the first discharge advances in a series of steps. It seems certain that a hitherto unobserved pilot streamer moves downwards comparatively slowly into virgin air, and that a bright streamer follows it with higher velocity, pausing whenever it catches up with the head of the pilot. This leader stroke lowers into the channel an appreciable part of the thundercloud charge, and it is followed by a positive streamer moving upwards along the same channel and neutralizing the charge in it. Subsequent strokes involve a fast 'dart' streamer advancing downwards along the ionized channel and followed by return strokes. Evidence is given that successive strokes involve separate charge-generating centres in the cloud. The mechanism of streamer advance is discussed. Where a previous supply of electrons exists, the mechanism of impact ionization leads to velocities of advance of the order observed for the dart and return streamers, assuming reasonable values for the electron fields at the tip of the advancing discharge. It seems probable that the same mechanism can also explain the slower advance of the pilot streamer into virgin air.

John Hunter as a Pioneer of Veterinary Science

THE annual oration of the Royal College of Surgeons commemorating the life and work of John Hunter, was delivered at the Mansion House on February 28, by Sir Frederick Hobday, emeritus professor of surgery, and formerly principal and dean at the Royal Veterinary College. This made a departure from the usual tradition that a member of the medical profession delivers the address.

Sir Frederick Hobday in his introduction remarked that he felt it appropriate that a member of the veterinary profession should be honoured by the invitation to deliver the oration, for John Hunter was one of the founders of the Royal Veterinary College in 1791. He is described as being "the life and soul of the undertaking", and with him were associated Sir John Banks, Sir George Baker, the Duke of Northumberland and certain members of the Odiham Agricultural Society, who collected the necessary funds, and they were instrumental in bringing to England Prof. Charles Vial St. Bel, of the Veterinary School at Lyons, to be the first principal of the London Veterinary College. The early and unexpected death of St. Bel caused much anxiety regarding the future of the College, and Hunter helped to tide over the emergency.

Sir Frederick Hobday then proceeded to review John Hunter's contributions to veterinary science. One of the first operations performed by St. Bel in Great Britain was the removal of accessory feet that grew from the fetlocks of the two fore-legs of a horse, and it is stated that Hunter personally assisted (he was surgeon at St. George's Hospital) and gave St. Bel "some useful and friendly hints". John Hunter was a genuine lover of horses, and has left some excellent advice upon their management and on the proper way to shoe colts in order to correct defects in the manner in which they may use their fore-legs. His observations on what is termed 'roaring' are of particular interest, and although he did not correctly recognize its cause (paralysis of the left laryngeal nerve), he clearly distinguished this condition from 'broken wind'. Hunter wrote, too, "upon the effects that medicines have upon horses", and was untiring in his studies of the anatomy and physiology of animals—from the mouse to the elephant—birds, reptiles, insects and fishes. The illustrations in his book entitled "Certain Parts of the Animal Economy" cannot be surpassed for clearness and accuracy even with the aids that are now available. His chapter on the glands between the rectum and bladder, the vesiculæ seminales, describes minutely the comparative anatomy and uses of these glands both in man and in numerous animals, and the alterations that ensue after an animal has been unsexed.

The body temperature of animals was another subject to which John Hunter devoted considerable attention. He performed an experiment in which he froze the edge of the comb of a cockerel and remarks that "when I cut off a little bit it did not bleed nor did the animal show any signs of pain"—pioneer work in the use of a freezing mixture as an anæsthetic.

Hunter's writings on digestion bear witness to his keen powers of observation, for he concluded that something secreted in the coat of the stomach acts upon the food and assimilates this to the nature of the blood. He had learnt that it is not possible to make a horse vomit, and recognized the different actions that medicinal agents have upon different species of animals. In regard to the last-named, Sir Frederick remarked that this could have been only through direct observation. Thus, morphine is a narcotic for man and the dog tribe, but produces disastrous delirium in the horse and cat; strychnine and mercurials are much more toxic for the cow and dog than for the horse.

In the realm of surgery, John Hunter's classical experiment of grafting a cock's spur into its comb is well known—definite pioneer work of the various grafting operations that are performed to-day. He also made a series of observations on the reunion of divided tendons.

In conclusion, Sir Frederick Hobday alluded to the importance to a country of its agriculture, its animals and arable products, and of comparative medicine in the fight against disease, for it is here that the medical man and the veterinary surgeon meet on common ground.

Crystal Structures of the Proteins

AN X-RAY STUDY OF PALMER'S LACTOGLOBULIN

By Dr. Dorothy Crowfoot and Dennis Riley, Department of Mineralogy, Oxford

THE crystallization of a lactoglobulin from the albumin fraction of cow's milk by Palmer in 1934[1] was notable both for the size and stability of the protein crystals and for their occurrence in two different crystallographic modifications. The stable tabular form occurs alone when salt solutions of the protein are dialysed at an initial *p*H of 5·8 followed by adjustment to a *p*H of 5·2 with dilute HCl, whilst direct dialysis at a *p*H of 5·2 against distilled water produces needles which may later recrystallize in the tabular form. We have been able to study the inter-relationship of these two varieties through the kindness of Dr. R. A. Kekwick of the Lister Institute, who gave us preparations of them both.

The X-ray measurements show that the two types of lactoglobulin crystals differ not only in crystal structure but also probably in their water content. The tabular crystals are evidently, even on superficial examination, heavily hydrated. They occur commonly either as plates {001} up to 0·3 mm. across and bounded by pyramid faces or as prisms elongated along [010] and showing (100) dominating. They prove to be orthorhombic but are very markedly pseudo-tetragonal, and appear isotropic when viewed along the *c* axis. The birefringence is negative, about 0·004. When these crystals are removed from their mother liquor they shrink visibly in the direction of the c axis, and the birefringence falls to less than 0·001. This shrinkage is accurately determined by the X-ray measurements which were carried out both on the air-dried crystals and on crystals mounted in their mother liquor. For the wet crystals $a = b =$ 63·5 A., $c =$ 145 A.; for the dry crystals $a = b =$ 59 A., $c =$ 105 A. The space group in the case of the wet crystals is $P2_12_12_1$, showing, in X-ray intensities as in dimensions, a close approach to the tetragonal space group $P4_12_1$, whence there are probably 8 molecules in the unit cell. There were too few X-ray reflections from the dry crystals to indicate the space group, but it seems most probable that this unit cell also contains eight molecules, but without water of crystallization.

		Pepsin	Hæmoglobin	Chymotrypsin	Lactoglobulin tabular	Lactoglobulin needle	Insulin	Tobacco seed globulin
Wet	a	116	109	½×99	63·5	63·5		
	b	67	63·2	67·8	63·5	63·5		
	Layer-spacing	9×51·2	50·2	65	2×72·5	2×62·5		
	Molecular volume (A.³)	67,000	174,000	55,000	73,000	63,000		
Dry	a		102	45	59	54	130	2×61
	b		56	62·5	59	54	74·7	2×61
	Layer-spacing		35	53·5	2×52·5	2×62·5	30·6	2×61
	Molecular volume (A.³)		101,000	38,000	46,000	46,000	50,000	455,000
	Shrinkage per cent		42	31	37	27		

The wet needle crystals occupy a place intermediate between the wet and dry tabular crystals. They appear to be exactly tetragonal, elongated along c. The cell dimensions are $a = b =$ 63·5 A., $c =$ 125 A., space group $P4_12_1$. The fact that the needles show positive birefringence suggests that they differ from the tabular form in the orientation of the molecules as well as in water content, and this is confirmed by the drying phenomena. There is little apparent change in shape or birefringence on exposure of the needles to air, but the very weak X-ray diffraction effects obtained from the dried crystals indicate a new unit cell with approximately $a = b =$ 54 A., and $c =$ 125 A.

The unit cell dimensions of the different lactoglobulin crystals suggest that in each case there are eight protein molecules in the cell, associated with different quantities of water of crystallization. Some difficulty was experienced, however, in making measurements of the crystal density to check this, owing to the great solubility of the protein crystals in salt solutions. A value of 1·257 was obtained in sugar solutions for the density of the wet tabular crystals, and this may be regarded as an upper limit for the density (*cf.* Adair and Adair[2]). It is in agreement with the presence of a considerable proportion of water in the crystals. It has so far proved impossible to measure the density of the needle crystals in any solvent, since even in sugar solutions the crystals rapidly imbibe liquid, with resultant swelling and loss of shape. The density of the dry tabular crystals in *o*-dichlorbenzene and toluene was found to be 1·27, which is lower than might be expected, probably owing to the occlusion of air in the irregular structure formed in the drying process. The molecular weight of the protein if calculated from this value and the cell dimensions given above is 35,300, or assuming the more probable density of 1·31 (that of dried insulin) 36,500. These values are in agreement with that obtained by ultracentrifuge measurements—about 39,000[3], within the limits of experimental accuracy.

It is of most interest to compare the crystal structure of these protein crystals with those previously measured, pepsin and insulin, and with hæmoglobin and chymotrypsin (recorded below). The similarity in cell dimensions extends also to the types of photographs obtained from wet and dry crystals of lactoglobulin. The wet tabular crystals give very beautiful X-ray pictures with reflections covering the whole field and extending out to spacings of less than 2·4 A. Those from the needle crystals are less good owing to their much smaller size. But with the dry crystals the photographs are very poor indeed, and this is evidently due to the poor orientation of the protein molecules in the collapsed structure. There are no X-ray reflections with spacings less than 20 A. The sharpness of the limit is reminiscent of that already observed on the much better X-ray photographs obtained from air-dried insulin[4], and suggests that in the insulin crystals also a certain degree of molecular disorientation prevails. As might be expected the crystal structure of dry insulin is of a very compact type, while in the wet lactoglobulin crystals, as in pepsin, the molecular arrangement must be loose and extended.

MOLECULAR WEIGHT OF A TOBACCO SEED GLOBULIN

By Dr. Dorothy Crowfoot, Dept. of Mineralogy, Oxford, and Dr. I. Fankuchen, Crystallographic Laboratory, Cambridge

In order to determine the structure of protein crystals from X-ray diffraction effects it is usually necessary to measure fairly large single crystals. An exception to this rule is the case of crystals belonging to the cubic system, for which powder photographs should provide sufficient data. A preparation of a cubic tobacco seed globulin isolated by H. S. Vickery of the Rockefeller Institute, New York, was given to us by Dr. D. M. Wrinch, and this we have examined by the X-ray method in the form of the dry powder.* The crystals were very small but well-formed isotropic octahedra.

Three powder lines were recorded on the X-ray photographs which correspond in spacing to the first three reflections from a cubic face centred lattice of dimensions $a =$ 123 A. This value permits us to calculate the maximum molecular weight of the asymmetric unit as 363,000, accepting the presence of only the four molecules in the unit cell required by the symmetry, and the density of 1·287 ± 0·001, measured in a sodium phosphate buffer at *p*H 5·0. Since the crystals lose 10·4 per cent of their weight when dried in a vacuum at 100° due to loss of what may be considered water of crystallization, the maximum molecular weight of the dried protein may be calculated as 325,000. This molecular weight is in agreement in order of magnitude with the sedimentation constant of $12{\cdot}7 \times 10^{-13}$ found for the same protein by J. Philpot in the Department of

---

*W. T. Astbury[5] has previously measured the large angle scattering, Biochemistry, Oxford, and is similar to those of other seed globulins, excelsin and edestin given by Svedberg as about 300,000[6]. The X-ray measurements provide some additional evidence to show that the units present in these proteins are of very considerable size, although at this stage we cannot exclude the possibility that the true chemical molecular weight of the tobacco seed globulin is a sub-multiple of 325,000.

An X-ray Study of Chymotrypsin and Hæmoglobin

By Prof. J. D. Bernal, F.R.S., Dr. I. Fankuchen and Max Perutz, Crystallographic Laboratory, Cambridge

We have recently been fortunate in obtaining well-developed crystals of two proteins—chymotrypsin and hæmoglobin. The former were prepared for us by Dr. Northrop of Princeton and the latter—methæmoglobin of horse—by Dr. Adair at the Physiological Laboratories, Cambridge. In both cases the crystals were well formed and large ($\frac{1}{2}$ mm.) and well suited for X-ray analysis.

Chymotrypsin crystallizes in thick diamond-shaped plates at first thought to be orthorhombic but afterwards discovered to be monoclinic twins. It was examined both in the native state in its mother liquor[7] and dried. The cell dimensions are $a = 49{\cdot}6$ A, $b = 67{\cdot}8$ A., $c = 66{\cdot}5$ A., $\beta = 102°$ for the wet crystals, and $a = 45$ A., $b = 62{\cdot}5$ A., $c = 57{\cdot}5$ A., $\beta = 112°$ for the dry. The space group in both cases is probably $P2_1$. The cell volumes are 219,000 and 151,000 A.[3] respectively. It is evident that very considerable shrinkage takes place on drying, nearly all of which is in the direction of the c axis. The density of the wet crystals could be measured by the methods of Adair and was found to be 1·277. If we assumed four molecules per cell this would give a molecular weight including water of crystallization of 42,300. In the case of the dry crystals it was unfortunately impossible to measure the density on account of the difficulty of removing crystallized salts. Assuming the density of the dried protein to be the same as that of dry insulin, namely, 1·31, the molecular weight is 32,000. This value for the molecular weight of a protein seems rather lower than is usually obtained by the centrifuge method, which, however, has not as yet been applied to chymotrypsin. It is difficult without a deeper analysis to say much about the inner structure of the crystals, but the extreme strength of (001) indicates a layer structure, while the weakness of (*hol*) when h is odd points to a pseudo-glide plane parallel to (010).

The hæmoglobin crystals were found to be monoclinic and usually twinned, corresponding very closely to the description given by Reichert and Brown[8]. The dimensions are $a = 109$ A., $b = 63{\cdot}2$ A., $c = 54{\cdot}2$ A., $\beta = 112°$ for the wet crystals and $a = 102$ A., $b = 56$ A., $c = 49$ A., $\beta = 134°$ for the dry. The space group in both cases is $C2$ with a face-centred pseudo-hexagonal cell. The cell volumes are 348,000 and 202,000 respectively. Here the shrinkage takes place apparently more by the increase of the β angle rather than by the shortening of cell edges. The density of the wet crystals is 1·242, which gives a molecular weight of protein and water on the assumption of two molecules per cell of 131,000. The molecular weight of the dry crystals has not been determined on account of the salt content, but taking the value of 1·26 based on that measured by Chick and Martin[9] for the closely similar serum albumin, the molecular weight is 77,000. The air-dried crystals still contain water. Taking the amount estimated by Haurowitz[10] as 9·6 per cent, the molecular weight of the dry protein becomes 69,000, which agrees excellently with the 67,000 found by chemical methods.

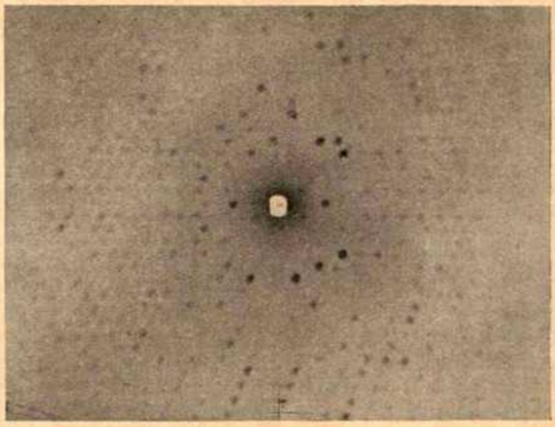

Fig. 1.

Wet hæmoglobin crystal; 5° oscillation about b-axis showing (*hko*)-zone at centre of photograph. Note the pseudo-hexagonal character of the pattern and the intensity of the reflections at high angles.

The molecular arrangement appears to be based on a layer lattice with a puckered pseudo-hexagonal network. In the dry crystals it is possible to arrive at a structure which accounts qualitatively for the

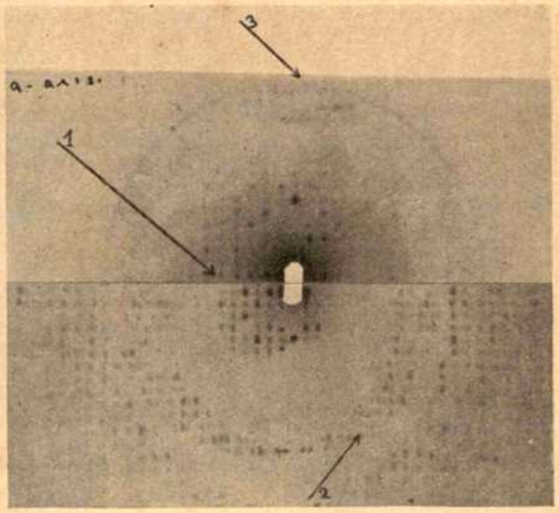

Fig. 2.

Comparison photograph of chymotrypsin: wet below and dry above; 5° oscillation about b-axis showing at centre of photograph the (*okl*)-zone. Note large difference of spacing of (00*l*)-reflections ($\uparrow_1$) and comparatively small difference of layer-line separation. The wet crystal was a twin; the (1*kl*)-reflections show doubling of spots ($\uparrow_2$). The rapid falling off of intensity in the dry crystal photographs should be noted. There is also the appearance of weak spots at a larger angle, corresponding to a spacing of 5 A. ($\uparrow^{8}$).

intensities of all the observed planes. In this structure the asymmetric unit is a half molecule of approximate diameter 35 A., linked with three others. The molecule observed in solution may be formed of two of these. The optical properties of the wet crystal point to the approximate parallelism of the hæmatin groups which lie approximately parallel to the (100) planes. As yet their position cannot be inferred, but owing to the two-fold axis of symmetry which the double molecule possesses, only two different kinds of hæmatin globin arrangements are possible. In the meantime, it is possible to draw some useful conclusions from the character of the photographs. In both cases the wet crystals showed perfectly definite reflections at spacings as low as 2 A. This proves the complete internal regularity of the protein molecules down to atomic dimensions. The dry crystals, on the other hand, show in the case of hæmoglobin no reflections of spacing less than 20 A, and for chymotrypsin, except for one or two weak reflections at 5 A., none below 8 A. Dr. Crowfoot had already noticed this phenomenon for insulin and more recently for lactoglobulin. The explanation is probably somewhat as follows. The intensity of a reflection from a protein crystal may be considered a function of three factors: the structure factor due to the position of the molecules, that due to the positions of the atoms inside the molecule, and a third factor depending on the regularity of arrangement. It is apparent that there is a general enhancement of spots in the regions of 9 A. and 4·5 A. corresponding to the two main reflections maxima of denatured proteins. In the dry protein, however, the irregularity is such that only the first of these is retained, the spots corresponding to the outer rim being generally too weak to register. If this analysis is correct, it follows that the change involved on denaturation does not require any considerable movement of atoms or amino-acid residues, but only relatively minor rearrangement together with almost complete loss of regularity, the dry protein representing an intermediate stage.

As can be seen from Fig. 2 the dried crystals of chymotrypsin show not only alterations of spacing but also of relative intensities of reflection. If we assume that drying takes place by the removal of water from between protein molecules, studies of these changes provide an opportunity of separating the effects of inter- and intra-molecular scattering. This may make possible the direct Fourier analysis of the molecular structure once complete sets of reflections are available in different states of hydration.

Already sufficient protein crystals have been examined by X-rays to be able to point to significant regularities. The table of lattice dimensions referred to three axes at right angles shows that the proteins fall into two groups: pseudo-hexagonal and pseudo-cubic, in both cases with a side of 60–75 A. This is of the order of twice the diameter of a protein molecule.

The work already done shows the wealth of new data that can be obtained by X-ray methods from reasonably well-crystallized proteins. The full advantage of the possibilities can, however, only be realized by work on a far larger number of protein types under different physical conditions, together with a more detailed application of crystal analysis.

Asymmetric-Sideband Broadcasting

AT a meeting of the Wireless Section of the Institution of Electrical Engineers on March 2, Mr. P. P. Eckersley read a paper entitled "A Quantitative Study of Asymmetric-Sideband Broadcasting". This paper directed attention to the fact that the progress of radio broadcasting is being hampered by the lack of a sufficient number of channels in which to contain the increasing number of transmissions. In the present state of the art, few, except local, stations can be received without interference from other broadcasting stations on adjacent frequency channels, unless the upper modulation frequencies of the wanted programme are severely attenuated. This inter-station interference can be reduced if all or part of one sideband of the transmitted spectrum is cut away; and it is the object of the asymmetric-sideband system of transmission to cut away part of one sideband without loss of the higher modulation frequencies and without introducing audible harmonic distortion.

Mr. Eckersley then gave a quantitative analysis of the phase and amplitudes of the sideband components and the effect of these factors in producing distortion. Curves have been derived, which show the required attenuation-constant of filters which cut away part of one sideband but produce no more than a constant, small distortion. A description was also given of practical tests in which the quality of reproduction obtainable from an asymmetric transmitter was compared with that given by orthodox modulation. It is claimed that while a highly trained ear may occasionally be able to detect some slight differences between the two types of reproduction when they are directly compared, no difference is detectable with modern broadcast receiving apparatus.

The last part of the paper showed that the asymmetric system has three possible applications to broadcasting as it is practised to-day. First, it could be used to allow carrier frequency differences of 11 or 12 kc./sec. without introducing any sideband overlap interference. Secondly, it could be applied to existing conditions in which the carrier frequencies differ by about 9 kc./sec., and it would then reduce inter-station interference to about one tenth of its present value. Thirdly, if the existing interferences are considered to be tolerable, then the differences between the carrier-frequencies of stations can be reduced to 6 kc./sec., without increasing the interference; this implies that one and a half times the number of stations working in Europe to-day on exclusive wave-length channels could be accommodated in the existing wave-band.

University Events

CAMBRIDGE.—The degree of Sc.D. has been conferred on C. H. Waddington, of Christ's College, lecturer in zoology.

The Faculty Board of Economics and Politics has appointed M. Paul van Zeeland, of Brussels, to be the Alfred Marshall lecturer for the year 1938–39.

The General Board has made the following grants from the income of the Worts Fund: £25 to F. H. Stubbings (of Emmanuel College) towards the expenses of a visit to Ithaca for archæological purposes; £12 to C. G. L. Shankland (Queens' College) towards the expenses of a visit to Italy to study the architecture of that country; £30 to L. H. McCabe (Peterhouse) towards the expenses of an expedition to Iceland to study the geography of that island; £100 to N. E. Odell (Clare College) towards the expenses involved in accompanying the Mount Everest Expedition 1938 for geological and glaciological study; £40 to G. E. Daniel (St. John's College) towards the expenses of a journey in France for the study of certain megalithic monuments in that country; £40 to F. J. Simonds (St. John's College) towards the expenses of a visit to Yugoslavia for a study of the ecology of certain insect larvæ in the streams of that country; £40 to M. Ballinger (St. John's College) towards the expenses of a visit to the Marine Biological Station, Tamaris, South France, to study the metabolism of the electric organ and muscular tissues of the torpedo; £60 to D. M. Carmichael (St. John's College) towards the expenses of an expedition to West Greenland to study the social habits and psychology of the Eskimo.

CAPE TOWN.—Prof. A. W. Falconer, professor of medicine in the University, has been appointed principal and vice-chancellor in succession to Sir Carruthers Beattie, who has retired.

LONDON.—Prof. I. M. Heilbron has been appointed as from October 1 to the University chair of organic chemistry tenable at the Imperial College of Science and Technology. Since 1935 he has been Sir Samuel Hall professor of chemistry and director of the chemical laboratories in the University of Manchester.

Mr. W. J. John has been appointed as from October 1 to the University chair of electrical engineering tenable at Queen Mary College. Since 1936, he has been University reader in electrical engineering at that College.

MANCHESTER.—Dr. Willis Jackson has been appointed Edward Stocks Massey professor of electrotechnics and director of the Electro-Technical Laboratories of the University as from September 29, when the appointment of Prof. Robert Beattie expires. Dr. Jackson is at present research engineer to Metropolitan-Vickers Electrical Co., Ltd.

MELBOURNE.—Dr. J. S. Turner has been appointed professor of botany. Dr. Turner is at present senior demonstrator of botany in the University of Cambridge.

OXFORD.—Dr. J. R. Baker, New College, lecturer in zoology, has been granted the degree of D.Sc. for his work in zoology and biological chemistry.

SHEFFIELD.—Dr. W. H. Pearsall has been appointed professor of botany in succession to Prof. B. H. Bentley, who is retiring at the end of the present session.

Science News a Century Ago

The Copper Mines of Cornwall

AT a meeting of the Statistical Society held on March 19, 1838, Sir Charles Lemon read a paper entitled "An Account of the Origin and Progress of the Copper Mines in Cornwall" in which he dealt with the history of the mines, the adoption of steam pumps and steam winding engines, production, employment, wages, consumption of coal and timber and the health of the workers. Newcomen engines were introduced early in the eighteenth century, but these had all been superseded by the improved engines of Boulton and Watt.

The total amount of coal reported to have been used in 1837 was 1,213,439 bushels, of 84 lb., and the total amount of water pumped by 60 engines was 31,141,800 tons. The production of ore and its value at various intervals between 1771 and 1837 was given as follows:

		Ore (tons)	Copper (tons)	Value of ore in £
1771	..	27,896	3,347	189,609
1800	..	55,981	5,187	550,925
1821	..	98,426	8,514	605,968
1837	..	140,753	10,823	908,613

The total number of persons employed in 59 mines was 10,624 men, 3,802 women and 3,490 children, and it was calculated that in 1836 about £482,000 was paid in wages. The average wages of a miner was 51*s*. 6*d*. per week.

Flooding of the Thames Tunnel

THE *Annual Register* for 1838 under the date of March 20 gives the following account of an irruption of the river into the Thames Tunnel on that day:

"One gang of labourers had been relieved by another when the water began rushing in with a loud noise. . . . In a few minutes the tunnel was filled. . . . Since the last irruption in Oct. 1837 the excavations had proceeded with more than usual rapidity owing to great increase in the enormous quantity of clay thrown down over the tunnel which formed an artificial bed of great consistency past which the works were advanced 3 ft. making in all 20 ft. added to the tunnel since the break-in six months before. At the beginning of the week the soil became loose, a vein of sand was encountered and it was found necessary to proceed with more than ordinary caution. On the night before the irruption the ground presented some indication of giving way, and much difficulty was experienced in going on with the excavations, the entrance of the sand and water being only prevented by the intrepidity of some of the old miners. Every precaution was consequently taken to prevent the loss of life which has sometimes attended the breaking-in of the river and the previous indication of danger, and the formation of the double gangways, enabled the workmen to get away without losing one of their number. Immediate measures were taken to stop up the aperture, which was soon ascertained to be of no very great dimensions. Several large loads of clay were thrown down immediately above the spot; and the shore engine employed to pump the water from the tunnel, which by the end of the month was completely cleared so as to allow of the works being resumed."

A New Tide Gauge

AT a meeting of the Royal Society held on March 22, 1838, Mr. T. G. Bunt gave a description of a new tide gauge constructed by himself, and erected on the eastern bank of the River Avon, in front of the Hotwells House, Bristol. In this apparatus a float was connected by a wire to a wheel and drum, 1/18 of the vertical motion of the float being given to a bar carrying a pencil which recorded the rise and fall of the water on a paper on a cylinder driven by an eight-day clock.

Dublin Zoological Society

"THIS institution," said the *Mechanics' Magazine* of March 24, 1838, "has in some degree overcome the difficulties whose occurrence seemed to threaten its very existence a short time ago. Extraordinary means, however, are obliged to be resorted to, in order to make up the deficiency of funds under which it labours. Among these is a series of lectures on Natural History delivered gratuitously by some of the most eminent physicians of the Irish capital, under the patronage of the Lord Lieutenant. It would be a pity indeed, if 'the second city in the Empire' should, like too many of our large provincial towns, suffer its Zoological Gardens to fall into decay after a short season of flattering success."

New Professorships in Paris

THE *Athenæum* of March 24, 1838, stated that "Dr. Duvernoy, of Strasbourg, at which place he holds a high situation in the university, has been appointed to the new professorship at the Collège de France, named the 'Natural History of Organised Bodies'. M. Poncelet, of the Academy of Sciences, has also been elected to the new chair of Physical and Experimental Mechanics, belonging to the Faculty of Sciences, and which has been created in consequence of the increasing manufactures and industry in France. A third chair has been instituted at the Jardin des Plantes, viz., that of Comparative Physiology, which has been given to the Chevalier Cuvier. To this list may be added the election of M. Audouin, the entomologist to the Academy of Sciences".

James Lowe's Screw Propeller

Two years after John Ericsson and Francis Pettit Smith patented their screw propellers, James Lowe (1798–1866) took out patent No. 7599 of March 24, 1838 for improvements in propelling vessels "by means of one or more curved blades set or fixed on a revolving shaft below the water line of the vessel". His propeller was tried in H.M.S. *Wizard* and afterwards in H.M.S. *Rattler* and H.M.S. *Phœnix*. In 1844 he brought an action against Penns of Greenwich for infringement, and the evidence showed that although Lowe was not the original inventor of screw propellers he was the first to use the combination of a segment of a screw, and of a segment applied to an axis below the water and with the segment totally submersed. Lowe, who was born May 13, 1798, was an apprentice of Edward Shorter, the London inventor of "the perpetual sculling machine", and became a merchant and smoke jack maker. He met his death by being run over by a wagon on October 12, 1866. He is buried in the churchyard at Ewell, Surrey.

Societies and Academies

Dublin

Royal Irish Academy, January 24.

B. N. SINGH: Cytoplasmic bodies in the oogenesis of the vulture (*Neophron percnopterus ginginianus*), with special reference to the effect of ultra-centrifuging on the oocytes of the pigeon. After ultra-centrifuging, the cytoplasmic bodies in the oocytes of the pigeon are stratified as follows: fat and cholesterol at the centripetal end; next, a layer of Golgi bodies, followed by a layer of mitochondrial yolk, and the mitochondria which are the heaviest components in the cell and occupy the extreme centrifugal end. No relationship exists between sudanophil fat and the Golgi bodies. Cholesterol bodies filter in from the egg membranes to the oocytes in the pigeon. No pre-existing 'vacuome' could be seen.

R. W. DITCHBURN: Diffraction by irregular gratings. The properties of gratings in which the spaces between the lines and the intensity scattered by a given line are not constants are discussed. It is shown that general expressions of a fairly simple type can be given for the diffraction functions but that it is difficult to apply these general expressions in the design of gratings. By computation and trial and error it is, however, possible to design gratings which have interesting and useful properties. In particular, it is possible to increase the resolving power considerably by the omission of some of the rulings of an ordinary grating. Examples of the application of the theory to line and echelon gratings are given.

ARCHIE LAMONT: Contemporaneous slumping and other problems at Bray Series, Ordovician, and Lower Carboniferous horizons in County Dublin. Accounts are given of submarine sliding of sediments. These appear to have been a surface expression of deep-seated tectonic adjustments. The Ordovician slumping corresponds with a horizon close to the transition between Caradocian and Ashgillian, and evidence of movement of a fault at this juncture is adduced. Carboniferous landslides, apparently set off by seismic agencies, were intensified during the Nassauian and Sudetic phases of mountain-building on the Continent. Anti-dune structures produced by anomalous marine currents are described.

J. SELWYN TURNER contributes a revision of the Carboniferous stratigraphy of the district.

Forthcoming Events

[*Meeting marked with an asterisk is open to the public.*]

Monday, March 21

Royal Geographical Society, at 8.30.—J. M. Wordie: "An Expedition to Baffin Bay and Arctic Canada in 1937".

Tuesday, March 22

Eugenics Society (in the rooms of the Royal Society, Burlington House, Piccadilly, W.1), at 5.15.—Miss Evelyn Fox: "Modern Developments in Mental Welfare Work".*

Birkbeck College, Physical Society, at 6.—E. G. Dymond: "Cosmic Rays in the Arctic" (Distinguished Visitor's Address)

Thursday, March 24

Royal Society, at 2.30.—Discussion on "The Application of Quantitative Methods to Certain Problems in Psychology".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Teacher of Chemistry in the Northern Polytechnic, Holloway, London, N.7—The Clerk (March 23).

Assistants (grade III—radio engineering) at the Bawdsey Research Station, Woodbridge, Suffolk—The Secretary, Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, N.W.1 (March 25).

Head of the Chemistry Department of the Coventry Technical College—The Director of Education, Council House, Coventry (March 26).

Inspector for Livestock in the Department of Agriculture for Scotland—The Secretary (Establishment Branch), 29 St. Andrew Square, Edinburgh, 2 (March 26).

Lecturer in Gardening, Biology and Elementary Science in the Caerlon Training College—The Higher Education Department, County Hall, Newport, Mon (March 28).

Assistant Adviser in Mycology at the Long Ashton Research Station—The Registrar, University of Bristol (April 2).

Assistant Lecturer and Demonstrator in Dietetics and Physiology in the King's College of Household and Social Science, Campden Hill Road, London, W 8 (April 11).

Analytic Chemist in the Medical Department of the Gold Coast and **Government Analyst** in Mauritius—The Director of Recruitment (Colonial Service), 8 Buckingham Gate, London, S W.1 (April 15)

Assistant Keeper in Entomology in the Manchester Museum, University of Manchester—The Registrar (April 20).

Lecturer in Physics in University College, Hull—The Registrar (April 23)

Lecturer in Physics and Lecturer in Mathematics in King's College, Newcastle-upon-Tyne—The Secretary to the Council (April 30).

Director of the National Institute of Agricultural Botany—The Chairman of the Council, N I A.B., Huntingdon Road, Cambridge (May 9)

University Lecturer in Geology in the University of Cambridge—Secretary of Appointments Committee, Department of Mineralogy and Petrology, Cambridge (April 19).

Research Assistant in the Oxford University Observatory—The Savilian Professor of Astronomy.

Investigator on welding to the British Non-Ferrous Metals Research Association, Regnart Buildings, Euston Street, London, N.W 1—The Secretary

Ethics and Ethnology

ALTHOUGH nearly fifty years lie between T. H. Huxley's Romanes Lecture on "Evolution and Ethics", delivered at Oxford in 1892, and the recent address on "Science and Ethics" by Dr. E. G. Conklin as outgoing president of the American Association for the Advancement of Science (see NATURE, January 15, p. 101), there is in them a striking congruity of outlook. In both, the ethical idea is paramount in the application of evolutionary doctrine to the problems of man's advancement. While for Huxley the blind struggle for existence, which had brought subhuman forms to the threshold of intelligence, henceforward in human society is dominated by moral and intellectual forces in a conflict—in the ultimate resort, one of ethical ideals—for Dr. Conklin determinism, to many an inescapable corollary of the modern approach to evolutionary problems, is mitigated by the selective powers of the human will, which can mould the forces governing human development to such ends as the ethical standard—the ideals of justice, truth, beauty, sympathy—may formulate. Nor does it affect materially the argument of either that the end to which the selective process is directed may vary with time, place and circumstance. Its virtue lies in the control which it exercises over material forces to make man potentially master of his fate.

That the ethical ideal, like the organic world, is subject to a process of development, and that it is variable according to chronological period, geographical distribution, and social environment is a matter of common observation. Morality, it has been remarked, is a question of latitude; and as Huxley pointed out, systems of ethics evolve. Nowadays modern ethnological inquiry would stress rather their relative character, the function of a specific ethical system in relation to a particular society and ritual of religious belief. Take, for example, some of the Bantu peoples of South or Central Africa, more especially those of Amazulu stock, which before effective control by British rule were organized mainly, if not entirely, for war. The whole ethical code with its 'religious' sanctions—penalties inflicted by spirits for the breaking of taboos—was directed to the avoidance or performance of actions affecting the success of the community in war. Among tribes, however, whose social organization was based on pasturage or agriculture rather than on war, the moral code was directed to the preservation of the community through the promotion of fertility. The diverse aims and preoccupations of the two types of community produced moral codes of an entirely different character, but each in complete harmony with its particular social environment. The detribalized natives of Africa illustrate the dangers of interference by well-intentioned, but ill-considered, effort with moral codes and attendant beliefs without effective substitutes which will ensure continued stability in that society.

The ethical system which derives its compelling force from reference to the claims and needs of a given form of society, affords no guidance for conduct as between man and man outside the group. In many primitive societies, members of the group alone are held worthy of the collective title of 'men'; and the implication of this group particularity absolves its members in contact with outsiders from the moral obligations and restraints observed in the relations of members of the group one with another. This is well illustrated in the history of the peoples pictured in the Old

Testament, in which the moral code imposed by the Decalogue is a matter for strict observance only as between the people of Israel. They are a 'chosen' people; and neither the sanctity of personal possessions nor the injunction "Thou shalt not kill" affect the warlike and aggressive followers of Jehovah when they fall upon and despoil a neighbouring tribe.

The teaching of Christ and the missions to the Gentiles inculcated a broader conception of the ethical relations which should subsist among the various branches of mankind; while the concept of catholicity was still further reinforced in the early Church through the influence of the Stoic doctrine of the brotherhood of man and the citizenship and *Pax Romana* of the Empire. The humanistic ideal, however, could not withstand such disintegrating forces as the Great Schism between the Eastern and Western Church, the growth of nationality and that reaction against freedom of thought which found expression in the Papal Bulls against heretics and the persecutions of schismatics, witches and such heathen as the Indians of America. The touchstone of the relations between individuals ceased to be in conformity with a standard resting on the broad basis of humanistic ethics and a sanction derived from religious belief, and became a question of adherence to an ecclesiastical organization, which claimed to be universal and of supreme authority in conduct and doctrine.

It is unnecessary to recall in any detail the disastrous consequences of this imposition of conformity to ecclesiastical authority in its effect in checking freedom of thought and intellectual progress for centuries—they are too familiar to need recapitulation; but recent pronouncements of members of the Church of England on questions amenable to the evidence of scientific investigation, for which at one period of the world's history they would have been burned at the stake, are some measure of the irreparable loss which science and humanity would have suffered had freedom of thought and the teaching of observation and experiment not resisted successfully the dictates of authority.

After fifteen years' deliberation, the Archbishops' Commission on Christian Doctrine has issued a report, which has been received with widespread astonishment, some bewilderment, and in certain quarters with something like dismay. The Commission disclaims judicial functions, nor is it unanimous: its findings are a statement of views on certain doctrinal matters, which have been the subject of controversy, held by various bodies of opinion within the Church of England and represented on the Commission.

The more outstanding of the Commission's pronouncements deal with such matters as the inerrancy of the text of the Bible, which it is stated in view of increased knowledge can no longer be maintained; the Creation, which it is acknowledged is regarded by many Christian thinkers as a continuous process; evil spirits, which may be taken symbolically, though, it is important to note, it is added that when Christ spoke of Satan, he may have shared the current belief of his time; miracles, a matter upon which some members believe it to be "more congruous with the wisdom and majesty of God that he should never vary the regularities of Nature"; the Virgin Birth, and the Resurrection in its physical features, which are interpreted symbolically.

This report will be a landmark in the history of Christian doctrine, even though it may be that the Rev. Dr. Inge, who seems to stand among those not least bewildered, is correct when he says that it "marks the position of King Canute's chair in this year of grace". It is unnecessary to stress the fact that it includes within the orthodox fold, or at least as maintaining a position not incompatible with Christian doctrine, those who now accept the more salient of the 'heresies' of scientific thinkers, which convulsed English society in the nineteenth century from the days of Dean Buckland down to the pitched battles which took place on the scientific positions of Darwin, Huxley, Tyndall and their successors.

Some critics would stigmatize the report as a capitulation to the forces of modernism and scientific materialism. This argues a failure to appreciate the findings of ethnological science and the history of religious belief. From such studies, the salient fact emerges that religious beliefs, when viewed objectively, are seen, like other component elements in human society, and most conspicuously, perhaps, the ethical standard, to be conditioned by time and place—the products of a specific tradition and culture, and in the course of time to undergo a process of development, or evolution in the more popular sense of the term. To illustrate this, it is unnecessary to go outside the Christian religion itself. The prominence given to the Virgin Mary in the Roman Church was undoubtedly fostered and reinforced by folk-memory of the cult of the mother goddess in Mediterranean belief; and hence the Reformation may, in part, be regarded as a revolt from an alien, southern form of ritual by peoples of northern Europe, to whom the belief in a God of Battles was more congenial. One of the effects of this diversion of emphasis in cult is to be seen in the predominating influence of the Old Testament in the life of the peoples of England and Scotland in the seventeenth century. This influence continued to be marked until superseded by the humanitarian ideals and missionary spirit of the New Testament, with the aid of philosophic doctrine, in the late eighteenth and nineteenth centuries.

The attitude, then, of the members of the Commission on matters of disputed doctrine must be construed as more than one of toleration only. It implies recognition of the fact that, just as in scientific investigation, hypothesis—for example, as to the nature of the universe, or as to the antiquity and descent of man—is subject to modification in the light of increased knowledge, so in matters of theological doctrine, orthodoxy is not static, but must vary in connotation with increase of understanding and a clearer view of the cosmic process. Further, that such understanding may bring about change in forms of belief, without affecting faith in the central doctrine of Christianity. The findings of the Commission would have been impossible a hundred years ago.

It may seem that to hold such a view of the relation of the evolution of theological dogma to the development of scientific thought is to make the validity of religious belief dependent upon the finite intelligence of man and to be incompatible with the tenets of a religion which takes its stand upon divine revelation. Yet is it not possible to regard both the growth of scientific knowledge and the development of dogma, each in its respective field, as two sides, two aspects of the same process—the search for truth, in which the Divine Purpose is revealed gradually to man *pari passu* with the preparation of his heart and intellect to receive it with understanding.

Whether the preparation of man's heart to accept the advances of science and the enlargement of theological doctrine, in other words the ethical ideal, has kept pace with development is more open to question. The prostitution of scientific discovery to the forces of destruction, and the economic dislocation, of which the consequences have more than neutralized the advantages of the application of scientific results and methods to production, would argue strongly to the contrary—and these are two only of numberless disharmonies. For this lag of the ethical ideal, the divorce of faith and reason, one of the most outstanding features of intellectual development in the nineteenth century, must be held largely responsible. It was, in fact, the diverging tendencies of scientific thought and theological doctrine in the hundred years before the Great War which for a large part of that period went near to sterilizing the more progressive thinkers in contributing to social advancement.

Dr. Conklin, in opening his address, stressed the advantage that might accrue from more effective co-operation between science and religion in the field of practical ethics. Many will feel that serious obstacles standing in the way of such co-operation have now been removed by the acceptance or toleration of certain of the principles fundamental in the scientific approach to problems of human betterment. The materialistic position into which scientific thought was virtually forced by nineteenth century orthodox rejection of evolutionary theory was saved from ultimate sterility and negation by a fervid belief in the perfectability of man. Notwithstanding a wave of pessimism now current, such optimism remains the philosophic postulate of much of the activities of research, justifying scientific wisdom of her children.

In the course of social evolution, the lesson of evolutionary ethics is that the ethical bond is accepted by an ever-widening circle from intimate family group to nation. In a modern world in which separatist ideas are paramount, this tendency to larger aggregation has suffered a check; and among modern social and intellectual forces, science alone speaks clearly in a tongue which meets with universal understanding. This has been shown in the recent fraternization of Indian, British and foreign men of science during the Indian Science Congress, though that meeting took place among peoples heated in political controversy. Yet religious toleration, at least among the more advanced, has now reached a point at which the English Church can not only unite with British Nonconformity in the attack on social problems, but also can seek a measure of union with the Eastern Church and other communions. The time has surely come for co-operation between religion and science in an endeavour to unite all men of good will, irrespective of creed, race and nationality, in seeking to arrive at a solution of the problems, fundamentally ethical, which now confront mankind.

Regiomontanus and his Calendar

Der deutsche Kalender des Johannes Regiomontan, Nürnberg, um 1474
Faksimiledruck nach dem Exemplar der Preussischen Staatsbibliothek. Mit einer Einleitung von Ernst Zinner. (Veröffentlichungen der Gesellschaft fur Typenkunde des XV Jahrhunderts—Wiegendruckgesellschaft, Reihe B: Seltene Frühdrucke in Nachbildungen, Band 1.) Pp. 80. (Leipzig: Otto Harrassowitz, 1937.) 20 gold marks.

FOR thirty years, the Gesellschaft für Typenkunde des XV Jahrhunderts has issued facsimile examples of print characteristic of that period: not for the sake of the text, but in aid of typographical study. These are being continued as Series A; but the Society has now taken over the publishing function of the younger Wiegendruckgesellschaft, and under the heading Reihe B it has begun, with the present small volume, a series of facsimiles (with suitable introductions) of complete printed works belonging to the fifteenth century. By means of this new series, the Society hopes to spread sympathy for its field of study not only among typographic scholars but also among persons learned in other fields, whose interest will be gained through reading characteristically fifteenth century works that are too rare in the originals for any but bibliographers and collectors to meet. This is an admirable plan; and to judge from this first example, it ought to succeed in its object; for the work now chosen is capable of interesting students of almost any aspect of the Renaissance.

Johann Müller, born in 1436 in the Franconian village of Königsberg, was variously called Johan von küngsperg, Hans von Königsberg, Joannes Königisberger, Joannes de Monte Regio, de Regiomonte, or, with the elevated simplicity which beseemed his fame, as Regiomontanus. He was one of those men of versatile genius—our own Robert Hooke, two centuries later, was of kindred stuff—who combine all sorts of practical ingenuity with accurate observation and with a strong capacity for abstract calculation in the service of concrete problems. A founder of the modern study of cometary movements and a fine general astronomer, the chief pre-Gregorian clarifier of the complex medieval calendar, and a founder of trigonometry (to mention no other activities), his masterliness was long acknowledged; and, but for his death at forty years of age, he might have put his name among the really great. A new account of his life is being produced by Prof. Ernst Zinner, director of the Observatory at Bamberg, and should afford a thorough and authoritative judgment.

Among Müller's subordinate feats was the setting up of his own press at Nuremberg, about 1472, mainly for the sake of printing his own and allied works correctly. Because of the need for methods of printing ruled tables of data, geometrical diagrams, accurately divided scales, and instruments of calculation, this was a courageous and innovating enterprise, especially at so early a point in the growth of the art. Müller's ingenuity was equal to the task; moreover, a young Augsburg man then in his employ, Erhard Ratdolt, soon carried his Nuremberg training to Venice, and later back to Augsburg, with such effect as to become the foremost astronomical and mathematical printer of the century; and he inaugurated this career by re-printing at Venice his former master's calendar, just as Müller himself had chosen as the first work for his press an astronomical treatise of his own former teacher at Vienna, Peuerbach. Müller's press lapsed in 1475 when he was summoned from Nuremberg to Rome by Sixtus IV to reform the calendar, and died there; but his quick technical success as a printer, no less than his merit as a chronologer and astronomical reckoner, can be gauged from the slim quarto under review.

Prof. Zinner gives a biographical notice and a clear and helpful commentary on the use and the vocabulary of the facsimile of Müller's (1474) printing of his German calendar, which is prefaced also by a short bibliographical note. Most fifteenth-century calendars were, like ours, for the current year only: they were single broadsides for putting on the wall, and sometimes bore New Year greetings in their initial letter. That of Regiomontanus, however, was a much more thorough-going and more valuable affair. How valuable may be judged from the facts that between 1474 and the end of the century it went through more than fourteen editions—Latin, German and Italian—and that it is recorded to have been used by Columbus and by Vasco da Gama on their voyages. Its first part is a semi-perpetual tabular calendar of twelve leaves, covering especially the two-cycle period from 1475 to 1513. Besides giving full data for the days of the week and month, Church feasts fixed and movable, the courses of sun and moon and the hour and minute of new and full moon at Nuremberg for any year of the period, it gives a conversion table for some sixty other localities, with their latitudes. (The only English place is Ochsenfurt, of lat. 53°—it is now 51° 46′—while Hibernia and Schotlant are both compressed to lat. 59°—about that of the Orkneys. But European cities are better defined.)

There follow orderly predictions of each of the sixty eclipses of sun and moon from 1475 to 1530, giving for each its date, times to the nearest minute, half-duration, and maximum obscuration to the nearest 1/12 diameter, this latter being also depicted by a large and exact woodcut in each case. The explanatory text follows, in a kindly Bavarian dialect—"nach meinem slechten tewtsche und chlainem vermögen"—and goes on, with tables, to define the paths of sun and moon up to 1532, including a short divagation on the best times for letting blood, which is the only relic of astrology admitted by this scientific observer.

Finally, there are instructions on the making and use of sundials and other chronological instruments, the woodcut patterns of which form the last four of the thirty leaves. One of these has three concentric disks with circularly graduated scales, two of which can be rotated, for the purpose of reading off corresponding values, on a central thread dangling from the leaf. The fourth cut lacks in facsimile what still survives in some originals as a most unusual component of any book, a doubly pivoted brass arm with a radial cord; but such an omission can scarcely be grudged, and is made good by Prof. Zinner's account of it in the preface.

The whole facsimile seems to be scrupulously exact (except, naturally, that it does not attempt to imitate the paper or the quiring of its original). Mention must also be made of the very agreeable roman fount in which the modern introduction is set. One's only qualm is caused by the price, which is likely to prevent the edition from doing what it was meant to do; and one may venture the hope that the Gesellschaft für Typenkunde will make the margin between cost and purchase-price as small as possible, so as to ensure the wide sale which this promising series deserves.

IRVINE MASSON.

Clinical Studies of the Heart

Diseases of the Heart:
described for Practitioners and Students. By Sir Thomas Lewis. (Department of Clinical Research, University College Hospital, London.) Second edition. Pp. xx + 297. (London: Macmillan and Co., Ltd., 1937.) 12*s*. 6*d*. net.

THE first edition of this book was published in 1933; it was reprinted in 1933 and in 1934, and translations have also been made into German, Dutch, Italian, Spanish and Portuguese, sufficient proof of the help which medical men all over the world have found in its teaching. A second edition has now appeared, though with few changes requiring note. The printing is on a slightly better paper which gives a most comfortable page for the reader's eye, but the illustrations are all unaltered and the only part that has been freely re-written is the chapter on pericarditis.

Research in heart disease has not slackened during the five years since the first edition came out, but Sir Thomas Lewis has not spoiled his book by yielding to the ordinary temptation to add to it every new theory or observation, irrespective of whether it has been fully tested and proved to be of value to the medical man. Even for that much debated and common malady, high blood pressure, he is content to describe its features and treatment, while for its cause he states with simple brevity, refusing all discussion of theories, that it has not yet been discovered.

The bane of most of the modern text-books of medicine is their incomprehensible comprehensiveness. Every rare event or complication is mentioned, to lie there for reference; every remedy that has been tried is listed; and all the modern as well as many of the older theories of causation are cited, often with only the labelling name of the sponsor of each as though that were enough for the sorting of such baggage without any description of contents. The accumulated mass hides the thought of the writer and chokes the reader's mind.

Lewis has deliberately avoided these faults. "An ideal that I have striven hard to attain is simplicity in teaching"—that is the wish emphasized in the preface to his book, and he has achieved it by restricting himself to a clear, though of necessity dogmatic, statement of his personal ways of thought and practice. But his views are those of a master of the subject, both in its experimental and clinical aspects, who for thirty years has continued to publish a succession of monographs and papers describing the rigid scientific analysis of problems dealing with the heart and circulation, and who through all that time has sought to translate such refinements of knowledge into practical modes that will guide thought and observation at the bedside to an equal scientific accuracy.

It may be recalled how Lewis's "Mechanism of the Heart Beat", an elaborate treatise on electrocardiography, was followed a year later in 1912 by a booklet of 100 pages on "Clinical Disorders of the Heart Beat", which gave to medical men the simple rules that all have since adopted for analysis at the bedside, without electrocardiograms, of the ordinary irregularities of the pulse. His present text-book on the whole subject of diseases of the heart summarizes the new attitude to those clinical problems that he himself has progressively taken and described in a series of papers with such clear argument that it has already been accepted by many leading teachers throughout the medical world. He writes with the aim of showing medical practitioners how to deal with living patients, of making them alert to judge each symptom that can tell of derangement of function in the living man; and so he refers but little to the older classifications of disease that were based on the isolated anatomical lesions to be revealed after death. Morbid physiology rather than morbid anatomy is the derangement that the clinician is invited to study and seek to correct. With all possible simplicity, this central idea is developed in its logical sequence through each chapter of the book.

For the reader who can forget much that he has been taught in the past, and look on his own clinical experiences in this fresh light, the book is an inspiring guide. Sir Thomas Lewis has thought as a physiologist, but his clinical work has always driven him to find out the meaning of physiology for practical medicine; and his matured teaching in this book has the conciseness gained by twenty years of testing and shaping it against the minds of his undergraduate students at University College Hospital. It is a model of what clinical science can achieve to help the practising profession.

Polymerization

Polymerization: and its Applications in the Fields of Rubber, Synthetic Resins, and Petroleum. By Prof. Robert E. Burk, Howard E. Thompson, Archie J. Weith, and Ira Williams. (American Chemical Society Monograph Series, No. 75.) Pp. 312. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1937.) 37*s*. 6*d*. net.

THE chemist at one time was mainly engaged in analytical activities; since 1900 he has set to work to make in the laboratory the less complicated natural crystalline substances of which he had discovered the constitution. Now that this task is largely completed, the urge is to polymerize, which means to build up very large molecules of amorphous colloid character, starting, however, from relatively simple substances. Promising fields of practical application of such effort have been found in rubber, synthetic resins and petroleum. This book deals with these; their magnitude and complexity are witnessed by the fact that four authors are required, whose names are attached to their respective chapters.

An immense amount of work has evidently been done in mastering the literature of the subject and sorting it into an accessible form, and perhaps chief praise will be given to the chapter headed "Catalysis and Polymerisation" by R. E. Burk, in which a table some sixty pages long is given, listing in alphabetical order the polymerization catalysts, the conditions under which they are used, the compounds polymerized and the results obtained.

Reference to this list is facilitated by a special index of the compounds. The research worker who uses it is able either to choose the best catalyst for a specific purpose or to ascertain the various methods of polymerizing a particular substance: references are given to the original papers. The chapter might appropriately be headed "Polymerization made easy" in view of the immense amount of time it is going to save for future workers.

Prof. Burk is responsible for the chapters on the mechanism of polymerization and the structure of polymers.

The second half of the book deals with the specific industries, rubber by I. Williams, resins by A. J. Weith and petroleum by R. E. Burk. The first two are engaged in the respective industries, and may be judged competent to give reliable and practical reports.

There is a useful theoretical chapter by H. E. Thompson on the relation between molecular structure and polymerization.

The book will undoubtedly command a wide and appreciative public among present and future 'polymerizers'.

E. F. A.

Entwicklungsbiologie und Ganzheit:

ein Beitrag zur Neugestaltung des Weltbildes. Von Prof. Dr. B. Dürken. Pp. vi+207. (Leipzig und Berlin: B. G. Teubner, 1936.) 6.80 gold marks.

THIS book is addressed not so much to the professional biologist as to the intelligent public and the philosopher. Its aim is to discuss anew what sort of mental picture we shall form of living organisms, and thus what kind of problems we shall formulate about them and what kind of answers we shall consider satisfactory. The question is discussed primarily with reference to the data of experimental embryology, which have so often led to similar disquisitions in the past. The fundamentals of our knowledge in this field, including the more important recent advances, are very clearly summarized in the middle section of the book, and this forms a valuable introduction to the subject, illustrated with admirable diagrams.

The philosophical point of view of the author is that of *Ganzheitsbiologie*, which corresponds more or less to what is known as organicism in Great Britain. This involves a rejection of both vitalism and mechanism, which, it is claimed, are characteristic products of the last century, with its over-emphasis on elementary particles. Biology, and the whole outlook of the present day, require a totally different method of approach, which is formulated thus: "The whole is not determined by the specific characters of its parts, but conversely the specific character of the parts depends on the primary whole".

There is probably, in spite of Viennese philosophers, a certain meaning and even truth in this statement. But what is required at the present juncture is an exact definition of what is meant by the 'primary whole'. Until this is provided, the statement is so vague that almost any conclusion can be drawn from it at will. In this book there creeps in at the end the deduction, which most scientific workers will have learnt to regard with some suspicion, that "Gemeinnutz geht vor Eigennutz". But in general the book is free from obvious politics.

An Introduction to Projective Geometry

By C. W. O'Hara and D. R. Ward. Pp. ix+298. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 12*s*. 6*d*. net.

THIS text-book should evoke in the student a realization of the infinite possibilities opened up by the many geometries included in the general scheme in which the classical geometry of his curriculum occupies a very subsidiary place. Starting with the initial propositions of incidence of lines and points, the synthetic method is developed up to the interpretation of the more complex properties of the conic. Then, co-ordinate systems are introduced projectively, to lead to the definition in projective terms of distance and angle. The various metrical geometries, both Euclidean and non-Euclidean, are discussed, and Euclidean geometry is shown to be a special case of the general projective metrical geometry.

The authors maintain that in two-dimensional projective geometry most of the fundamental ideas pervading the whole subject are developed, and that an introduction to these ideas in the simplified fields of points and lines is better than in the more complicated fields of the higher dimensions. In the last chapters, possible developments are indicated and the application of the subject to physical geometry is shown. Furthermore, the part played by the special theory of relativity in the theory of physical geometry is shown to be an application of the principles which have been developed in the book.

The book is intended for scholarship candidates and first-year university students. A. v. Z.

Einführung in die chemische Physiologie

Von Prof. Dr. E. Lehnartz. Pp. viii+420. (Berlin: Julius Springer, 1937.) 19.60 gold marks.

AN enormous amount of information has been packed into this attractively produced volume. The first hundred pages give the chemical structure of all the more important substances found in living tissues. Forty pages are devoted to physical chemistry. Vitamins, hormones and enzymes are then discussed in separate sections, and the last 130 pages are devoted to metabolism. Generally speaking, the book is very complete and up-to-date (1937) and is clearly based on a wide knowledge of the German literature, but the work of Rowntree on the thymus, for example, is omitted, presumably because the results were published in America. The author is to be congratulated on the tables he gives showing the distribution of vitamins in different foods. A few years ago such tables were vague and qualitative, but so much progress has been made recently, that it is now possible to give the actual concentrations of vitamins A, B_1, B_2, C and D in terms of the weight of vitamin in 100 gm. of material.

The main users of this book, in Great Britain, at any rate, will probably not be biochemists, but those others whose research work sometimes brings them in contact with biochemical problems. Information is easy to find and references are given, not to original papers, but to more complete monographs.

Schwingende Kristalle:

und ihre Anwendung in der Hochfrequenz- und Ultraschalltechnik. Von Prof. Dr. Ludwig Bergmann. (Mathematisch-Physikalische Bibliothek, Reihe 1, Band 93.) Pp. 47. (Leipzig und Berlin: B. G. Teubner, 1937.) 1.20 gold marks.

THIS is a remarkable *tour de force*. In five brief but lucid chapters on piezo-electric phenomena, piezo-electric crystals in high-frequency fields, the application of oscillating crystals in high-frequency technique and electro-acoustics, the applications in ultra-sonic technique and the significance of ultrasound in science and technics, the author presents a simple and amazingly complete picture of the applications of oscillating crystals. The book has a wealth of illustrations (more than one per page of text), of which neither half-tones nor line diagrams suffer any loss in value from the smallness of size which is imposed by the attractively compact form of this popular monograph.

Crop Production without Soil

By Prof. W. F. Gericke, University of California

THE tenets of water culture are known to plant physiologists from an extensive literature. The first papers appeared more than three-quarters of a century ago. Although water cultures are used widely in experimental studies of plant physiology and soil science, the literature is singularly devoid of any suggestion of the economic possibilities of the method—crop production without soil. A brief paper in 1929 was the first announcement that crop production by water culture is practicable[1]. Beginning in 1935, a number of growers, convinced that the method had possibilities, established the first production plants; these are under the author's supervision and, although organized as commercial ventures, are administered as the author's experiments. The largest plant covers two acres.

While a history of the development of the economic use of water culture would not be complete without mention of the laboratory experiments, nevertheless the idea was not born wholly out of the laboratory concepts. Crop production by water culture is not a large-scale use of previously employed technique. Much of the idea was developed from extra-laboratory observations and considerations, from studies and analyses of the physiological and ecological conditions of practical farming operations; and these gave the cue to the devising of suitable techniques, and providing favourable ecological conditions. The technique of the laboratory as heretofore used and that of practical operation differ not only as to physical features but also primarily in physiological concepts and interpretations.

With the establishment of the economic use of water culture, it appeared well to have a word that would distinguish between the two uses. It was found that 'aquiculture' had already been appropriated. 'Hydroponics'[2] was then suggested by Dr. W. A. Setchell, University of California, to designate the "art and science of crop production in liquid culture media". The term 'water culture' can thus be reserved to its historic use and meaning—the growing of plants in nutrient solutions for experimental studies in plant physiological laboratories.

In order to prove the economic feasibility of water culture, evidence was needed that yields sufficiently large were possible to warrant the investment for the equipment required. Consequently, experiments were designed to obtain data on productive potentiality of unit areas of nutrient water surface so that comparison could be made with known production by agriculture.

The 'limiting factor' in yields by agriculture in climates suitable thereto are usually pedological. If these inhibitions could be overcome by water culture, then it should be possible to increase yield per unit area of surface by closer spacing of the plants. Increase in yield would then simply be a function of increase in stand, granted, of course, that the individual plants grown by water culture are as good as those grown by soil. Experiments showed it was possible to use closer spacing for some crops in hydroponic production than in field production; this gave, therefore, expectation of corresponding increase in yield.

Crop production comes as the result of many processes, some of which oppose each other in operation. Ideal conditions could not be prescribed from the findings of laboratory experiments, because these were designed to study specific plant processes as phenomena more or less detached from their agricultural concept and interpretation. Ideal conditions for crop production are virtually compromises between or among various opposing elements and represent essentially the best coordination which the circumstances permit of all important growth-affecting factors. The physiological basis of hydroponics lies in the functions of cultural technique and equipment, designed to obtain yields of crops which, when measured by the standards of the farmer, compare favourably with those of agriculture. Heretofore no comparison was possible because the scale of the water culture experimentation employed in plant physiology laboratories was far too small and restricted to warrant interpretation of data in the standard of the farmer's 'yield per area'. But more serious, however, was the fact that the ecological conditions created by the technique used was quite foreign to the natural pattern for plant growth, so that the data had very restricted interpretation and application. Essentially it was not the physical limitation of size of equipment used which obscured the productive potentiality of water culture, but rather that small size created unfavourable ecological conditions. These in turn created physiological limitations.

While the importance of climatic and ecological conditions to crop production is so widely and generally recognized that it seems presumptuous to make allusion thereto, nevertheless, in view of the historic use of water culture in scientific studies, it appears not out of place to direct attention to the conditions under which the experiments were conducted, and invite comparison of the laboratory with that of Nature. Essentially, the temperature of the soil, except the surface layer, does not vary from day to day; the air temperature varies according to the diurnal changes of solar radiation. It follows, therefore, that the gradient of the root-top temperatures of the plants must change therewith. Complete reversal of gradient comes in the course of twenty-four hours wherever a marked difference prevails in the air temperature of day and night. It is obvious where plants are grown in small containers set on laboratory benches that either a maintained or changing temperature of the room creates a different ecological condition from that which exists in Nature with respect to the root-top gradient. The different parts of most economic plants do not have the same climatic requirements, and consequently cultural technique which exposed the different parts to the same temperature environment cannot be expected to favour growing conditions. The more or less rhythmic change in root-top gradient by virtue of change of the air temperature from day to night and constant root temperature, is an ecological condition that the laboratory climate did not provide.

Classical water-culture experimentation required pure or refined chemicals, pure water, and glass or glazed earthenware containers which resisted solvation. The nutrient solutions were therefore of fairly well-defined character and composition. Obviously these materials are economically prohibitive for economic use of water culture. Consequently investigation had to be undertaken to determine the suitability of ordinary and less expensive materials. Hitherto untried materials had to be studied: crude chemicals and ordinary ground water for the nutrient solutions; building materials—concrete, wood, sheet metal, and various plastics for containers; and various kinds of vegetable litter for the seed-bed.

The equipment must supply the functions of a fertile soil—supply vegetation with water, with the necessary elements, and provide support to hold the seed and growing crops in proper juxtaposition to the environment (Figs. 1 and 2); the feeding roots in the water, the root crown in moist porous media above the water, the leaves in the air.

Basins now in use are constructed of the following materials: concrete, wood, sheet metal (iron) and various asphaltic preparations. The concrete basins constructed as trays range from 2½ ft. to 6 ft. in width with 50 ft. as the maximum length of single units. In some cases units are joined end to end, making even longer basins. Also basins 50 ft.×100 ft., providing continuous water surface of 5,000 square feet, are being tried. Wooden basins range from trough-like structures 1 foot wide and 40 feet long to flat tanks 12 feet wide and with length sufficient to provide 1/200-acre water surface in single units. Black iron sheet metal has proved serviceable for smaller basins; the largest used are 2½ feet wide and 10 feet long. Certain asphaltic preparations, where proper care was taken in construction, have made fairly serviceable equipment—that is, more or less durable. The depth of the basins range from 4 inches to 8 inches; 6 inches is probably the most satisfactory for most crops.

Remedial measures taken to overcome harmful substances in the materials were as follows. For the alkalinity of the concrete, leaching with water, treating with acid, and coating with non-toxic, water-resistant paints proved effective. For unknown organic substances that may diffuse from wood, brush treatment with strong alkali solution gave good results. Black iron sheet metal gave no trouble—it is conceivable that iron which has appreciable quantities of zinc, copper, manganese, nickel, and presumably other metals, would give trouble unless the iron is coated with a non-toxic paint or enamel. Some of the asphaltic preparations used were found to be toxic and care must, therefore, be taken in the choice of all asphaltic or bituminous materials which are used as plastics or to coat and waterproof equipment.

While the size of basins in the several plants was determined wholly from mechanical considerations, observations, however, have shown that size has physiological importance. This was suggested in several ways, but the information available does not yet warrant a definite statement.

The seed-bed is a mat of vegetable litter—excelsior, straw, sawdust, peat moss, etc., mounted over the surface of the nutrient solution. It rests on wire netting strongly secured to a portable frame. This rests on the top of the basins. The seed-bed provides support for the seed and growing plants, and by protection against sunlight inhibits the growth of algæ. It also protects against desiccation, and extreme temperature fluctuations. The nature and quantity of litter used reflects itself in the water-air properties of the seed-bed and thereby affects ecological conditions. The greater the amount of water that can be held in the seed-bed, compatible with good air supply therein and with other plant requirements, the less fluctuation will there be in the temperature of the roots and of the root-crowns of the plants with changes in the air temperature, because of the high specific heat of water. The root-crown requires different ecological conditions from the feeding roots immersed in the solution. Classical technique with the plants held in the solution by a nonporous support precluded the attainment of these important conditions.

The elements essential to plant growth in liquid culture media are generally known. These elements can be grouped into three classes. First those required in fairly large amounts, which can be supplied in considerable excess without toxic effect, and each of which is absorbed in varying quantities, so that the composition of the plants will thereby vary; these elements are nitrogen, phosphorus, potassium, calcium, magnesium. Their range as possible variants in the plant composition must be considered in devising formulæ. In the second class is the element which can be supplied in large excess without toxic effects and is not absorbed in markedly varying amounts, hence is a minor variant in plant composition. This element is sulphur; the sulphate, therefore, becomes in effect a balancing agent. The third class includes the elements required in small amounts and which are toxic if the concentration exceeds certain low values—fractions of a part per million. These elements are iron, manganese, copper, zinc and boron.

The salts should be chosen so that mixtures can be made which will conform in a general way to the proportions found in the composition of the plants, considered as the aggregate of the compositions of different parts. The salt which provides the cation required in largest amount shall provide the anion required in largest amount. Likewise the cation required in smallest amount can be supplied with the anion required in smallest amount, and for those elements between these extremes, the same principle holds. Thus, potassium nitrate, calcium phosphate, and magnesium sulphate are the chief commercial sources of the major elements. In the original experiments, magnesium phosphate and calcium sulphate were used instead of the last two of the above, but, inasmuch as the desired combinations can also be obtained from chemicals already extensively used as land fertilizers, the former set is recommended. Whenever it is desirable to have some combinations which the above three salts cannot provide, a fourth salt can be added; sulphuric acid is added to the mixtures to obtain any required reaction. Sulphates as already noted are not absorbed in great excess of the plants' need and, therefore, large quantities can be used if necessary. The sources of the minor elements is essentially immaterial, unless plant products relatively high in

TANK OF TOBACCO.

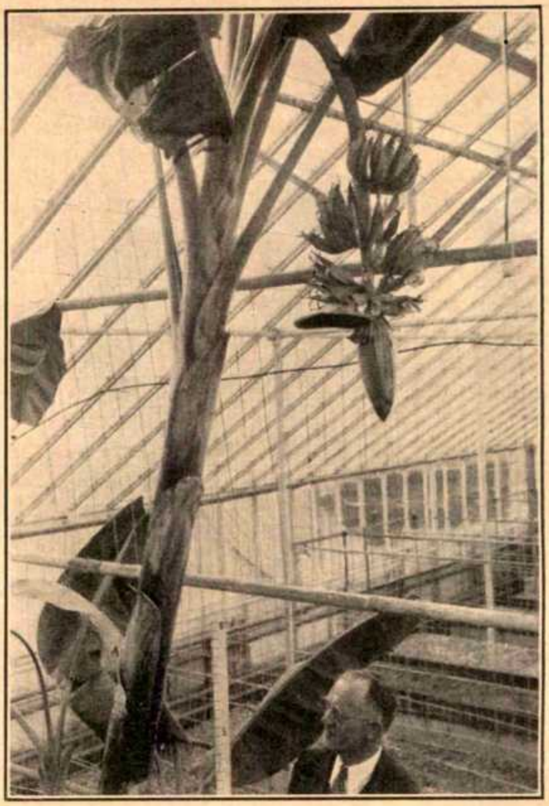

Fig. 2.
BANANA, ONE YEAR FROM BUD.

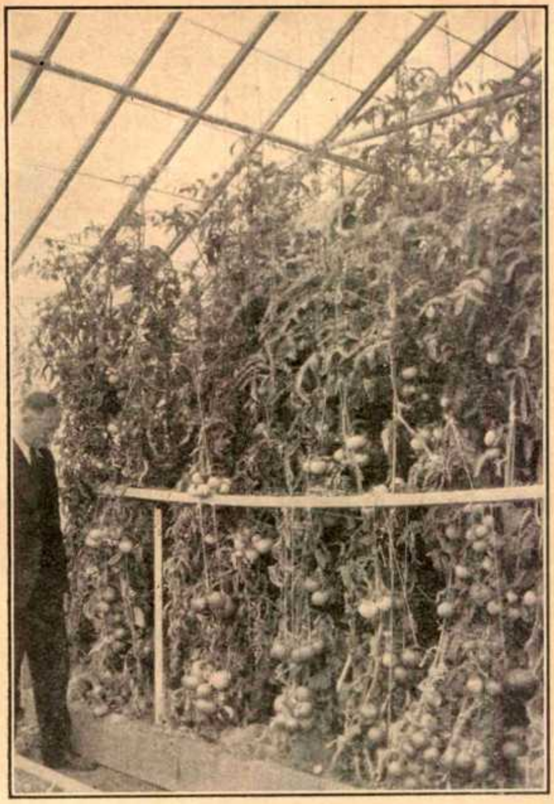

Fig. 3.

TOMATOES, 4¾ MONTHS AFTER PLANTING.

some of these elements are desired. In such cases one would choose the least toxic forms, which in some cases would be organic compounds.

The purpose of having the nutrient solutions conform as nearly as possible to the composition of plants, is to preclude excessive absorption of certain elements causing an abnormal composition. The fact that plants vary as to composition is in itself evidence that nutrient solutions, somewhat different in chemical composition from those compounded by the principles stated above, will support plant growth with more or less satisfactory results. But excessive absorption of any element, especially in the early growth stage, may have unfavourable effects on subsequent plant activities. On the other hand, the early growth stage is also most labile, permitting use of stimulatory conditions which can be very beneficial if not too greatly prolonged. For example, a relatively large supply of certain elements in the culture during the early growth stage, which in case of nitrogen could be supplied both as cation and anion, and more or less complete absence of them in the latter growth period, will be more effective for certain crops than a maintained supply—the quantity absorbed being equal in both cases.

Answer to the question "How much plant food shall be added to a given quantity of water ?" can be given by the description of experiments with some of the crops, for example, with tomato (Fig. 3) : 20 plants set in a basin 10 feet long, 2½ feet wide, and 8 inches deep (thus 16⅔ cubic feet of water) received nutrients in 1-pound lots, supplied as a mixture of dry salts. When the plants were about two months old, the nutrients were practically exhausted and then another pound was added. Subsequent additions were made at shorter intervals, 7 pounds being the total amount supplied; but the solution was exhausted two months before the experiments were concluded, being then one year old. (The average yield of ripe fruit per basin was 306 pounds—more than five sixths of the total was harvested nine months after planting. There were four basins, each a different treatment; the largest yield was 532 pounds. The basins, including space between, occupied 130 square feet of greenhouse floor.) No difference was noted when smaller applications were made at frequent

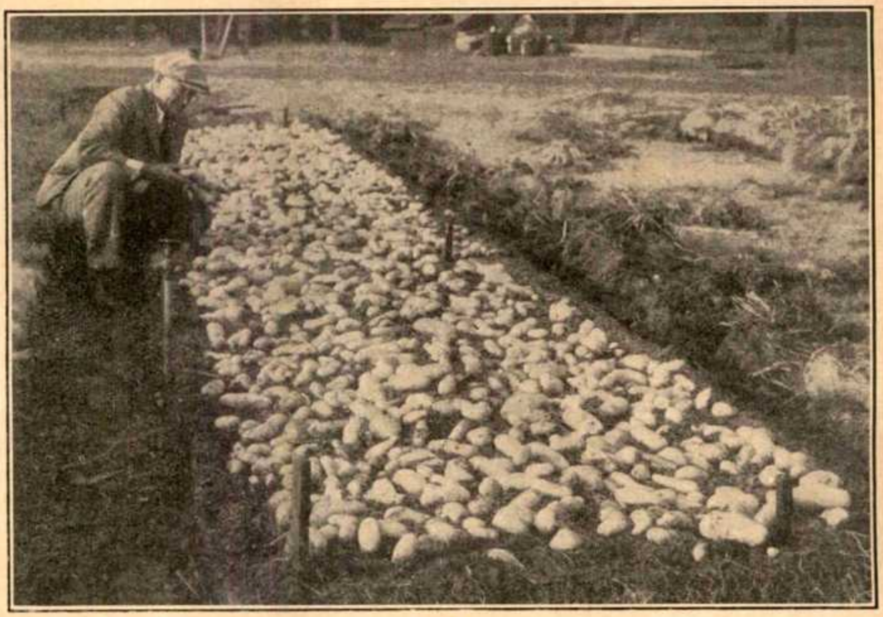

Fig. 4.

HARVEST OF 1/100-ACRE POTATO CROP, 18 WEEKS AFTER PLANTING.

intervals or larger applications at less frequent intervals. Apparently any concentration within the range defined for the lower limits of about half a pound, and the upper limit of about two pounds per 16 cubic feet of water, gives satisfactory results. This means that the stirring in of additions of nutrients was not necessary; the mixture was merely added at one point. Obviously there is a practical limitation to the distance salts will diffuse and consequently appropriate means must be employed where large basins are used.

A field of 1/100 acre area planted to potatoes produced a yield of 24·65 bushels, or 1,479 pounds (Fig. 4); 40 lb. of chemicals was used. This experiment was in 1934. In subsequent trials each year thereafter, the above-stated large yields were not obtained; apparently certain features of the techniques, ideal in 1934, did not produce ideal growing conditions in the subsequent tests. I believe, however, that the technique can be designed to obtain consistent results with the potato.

The retail market price of the chemical used in largest amounts, and the most costly, namely potassium nitrate, was 70 dollars per ton. Chemicals were of the grade used in compounding fertilizers for land.

The greatest item of cost in crop production by hydroponics is the investment in basins. Also the cost of the chemicals will be a major item in some crops. For example, about two pounds of chemicals were required to produce four pounds of dry wheat grain. Even though the yield per unit area of water surface in basins of the size mentioned for tomatoes was exceptionally high (computed to acre basis it was 142 bushels), the ratio of the quantity of plant food required (at first glance one may think this quantity too high; the weight of oxygen accounts for the apparent large quantity of plant food required) to that of yield obtained makes the cost of production of wheat and other crops that are predominantly 'dry matter' prohibitive by water culture under present conditions. Crops the marketable products of which are characterized by high water, starch, or sugar content, give promise in an economic appraisal of production by hydroponics.

It is, of course, not inconceivable that industry may develop and manufacture equipment at markedly greater economy than prevails at present, thereby increasing the number of crops that can be grown economically.

There are no specific formulæ or cultural techniques that can be prescribed to be followed too literally because of the somewhat unknown character of the materials and equipment that will be used; cultural technique must be designed to meet the conditions where the crops are grown. The principle of making the adjustments, the elucidation of the physiological basis for all features of the method, together with concrete description and data of experimental plants, need to be made available for the guidance of prospective hydroponicists. To provide this is the programme of research now being pursued.

Centenary of the Atlantic Steam Ferry

IN April 1838, the paddle steamer *Sirius*, 703 tons gross, won for herself the distinction of being the first vessel to cross the Atlantic Ocean under continuous steam power. To celebrate the centenary of this notable achievement, a special exhibition, "One Hundred Years of Transatlantic Steam Navigation", is being held at the Science Museum, South Kensington, and will be open until mid-September, to show in outline the developments that have marked the growth of this service. An illustrated handbook bearing the same title (London: H.M. Stationery Office. 6*d.* net) prepared by Mr. H. P. Spratt, the Museum officer responsible for the organization of the exhibition, gives a brief account of the history of the Atlantic steam ferry together with descriptive and historical notes on each of the steamships represented. These exhibit the striking developments which have taken place in naval architecture and in the methods of steam propulsion.

The change from wooden hulls, first to wrought iron construction and finally to steel, is exemplified in the size of the vessels and in new methods of construction. Paddle wheel propulsion gave way to single screws; twin, triple and quadruple screws followed in quick succession. The early engines derived most of their power from the condensation of the steam, and the nature of the evolution was first to simple expansion engines and then to compound, triple and quadruple expansion engines which, in their turn, have been superseded by the Parsons direct-drive, then single-reduction and now double-reduction turbines. It is to be remembered that each of these developments has been due not only to the progress of design but also to the improvements in ancillary departments, such, for example, as the manufacture and treatment of steel and other materials and in the production of accurately cut gears. As a means of visualizing the increase in size of the vessels, it is pointed out that the hull of the *Britannia*—the first of the Cunarders, 1,156 tons, built in 1840 at Greenock—could be fitted into the restaurant and foyer of the R.M.S. *Queen Mary*.

A visit to the exhibition is most instructive, as it epitomizes in the models which have been gathered together from various sources these and other aspects of the technical developments which the century has witnessed. A visit is the more desirable in that such an opportunity of seeing so many closely related models in so favourable a setting can only occur at rare intervals. As the models are, with a few special exceptions, to the same scale of 1 to 48, it is possible to obtain a clear idea of the relative sizes and forms of these historic vessels. Among them are several foreign ships, notably the *Bremen*, the *Conte di Savoia*, and the *Normandie*, while another exhibit which has a special importance as the representative of steam's competitor in ship propulsion is the model of the Swedish diesel motor-liner *Gripsholm*. The *Conte di Savoia*, built at Trieste in 1931, was the first Atlantic liner to be fitted with gyroscopic stabilizers. These were made in England and the installation is calculated to limit the roll of the ship to 3° on either side of the vertical.

As to which is the most interesting vessel represented, opinions differ, but the *Great Eastern* (1858) has some claim as being a premature leviathan conceived and built forty years or so in advance of practical experience. She was designed by Brunel and was about five times the size of any then in use. Built at Millwall, many unsuccessful attempts were made to launch her, and finally she was launched sideways into the Thames. A unique feature was that she was propelled both by paddle wheels and a screw propeller. The paddle engines of 3,411 I.H.P. had four oscillating cylinders and received steam at 24 lb./in.^{2} from four double-ended tubular boilers of box pattern. The screw engines of 4,886 I.H.P. had four horizontal direct-acting cylinders and received steam at 25 lb./in.^{2} from six double-ended tubular boilers. Though she had no commercial success as a liner, she did most valuable work between 1865 and 1873 in laying a number of submarine cables. Not until the *Oceanic* was built in 1899 was the size of the *Great Eastern* exceeded.

As a further mark of the importance of the occasion, a lecture entitled "The Centenary of Transatlantic Steam Navigation" was delivered before the Newcomen Society at the Science Museum on March 16 by the president, Engineer Captain E. C. Smith, in which he dealt particularly with the construction and experiences of the early vessels on this service. Prior to 1838, many voyages across the Atlantic had been made by steam-engined vessels, but so far as it is known, all were made partly under sail. The first three to cross by steam power were the *Sirius*, built for the London and Cork service, which arrived off New York on April 22, 1838, the *Great Western*, built for the Atlantic service, which arrived on the next day, and the *Royal William*, also built for the Atlantic, which after some misfortunes completed the crossing on November 23. These vessels were, in a sense, sailing ships, as they carried sail and took advantage of the wind, but they were intended when necessary to steam against wind and sea. Therefore, although in effect sailing ships fitted with engines, they embodied important constructional modifications so that they could carry the machinery stresses and bear the severe shocks inevitable in a seaway. Sleepers or platforms were built in to carry the boilers and engines, strong beams were necessary to support the paddle shafts and the sponsons housing the paddle wheels. Sir Robert Seppings, surveyor to the Navy, was responsible for many of the devices adopted, and it was he who introduced a method of fitting the frames close together and caulking them to form a solid hull before the external planking was fixed. He also devised an arrangement of internal diagonals, which later took the form of diagonal iron bars, so as to make the hull a rigidly trussed structure.

Early engines were very similar to the land engines made by Boulton and Watt, of the two cylinder side-lever type with cranks at right angles, and used steam at a pressure of 2–5 lb./in.^{2} Condensers were essential at first as the bulk of the power was derived from the vacuum; later they were discarded and afterwards were re-introduced. Sea water was used in the boilers, which were practically rectangular tanks with internal flues. It was an important duty of the engineer to keep the density of the water low to prevent incrustation. Three methods were in use, the earliest being to stop the engines every third or fourth day, empty the boilers and refill from the sea. This was superseded by frequent blowing down which, in turn, gave place to the use of brine pumps.

The reprint of the lecture contains extracts from the "Field Papers" preserved in the Science Museum Library, which give much information not obtainable elsewhere on this subject.

A contemporary view of the prospects of the Atlantic crossing under steam appears on p. 566 of this issue.

Obituary Notices

Mr. T. W. F. Gann

We regret to record the death of Mr. Thomas William Francis Gann, archæologist and explorer of Central America, which took place in London on February 24, in his seventy-first year. He was the son of William Gann of Whitstable, and was born at Murrisk Abbey, Co. Mayo, the home of his mother, who before her marriage was Miss Rose Garvey.

Gann was educated at King's School, Canterbury, and at Middlesex Hospital, where he qualified as M.R.C.S. and L.R.C.P. in 1890. Later he went to Central America with a medical expedition to relieve distress after an earthquake in Guatemala, and from that time forward his life was devoted to Central American studies. He entered the Government service of British Honduras at Belize, becoming in due course principal medical officer of the colony and a member of the Legislative Council.

Although Gann was keenly interested in the study of tropical medicine, he was even more deeply devoted to study of the archæology of the Mayan civilization of Central America. Taking advantage of the numerous journeys to various parts of the colony, which it was necessary for him to make, he explored the country for previously unrecorded ruins, at the same time observing the character and customs of the natives, which he appreciated might serve to throw light on the peoples of the ancient civilization. It was not long before he was recognized as an authority on Central American archæology. He contributed papers to the British Association and the publications of the Smithsonian Institution of Washington, and later was appointed lecturer on Central American archæology in the University of Liverpool. In 1926 he represented the British Government at the International Congress of Americanists in Rome.

After the Great War, Gann's work, already recognized by specialists, became more widely known through the travel books of a semi-popular character which appeared annually over a number of years. In each of these he described a journey of archæological exploration which he had made in the preceding year, and on nearly every occasion he had some outstanding discovery of previously unknown ruins to record. Of these, one of the most remarkable was the city of Coba, with its wonderful stone causeway of approach, extending for many miles. He also discovered some important date-inscribed stelæ, one of which was deciphered as giving the earliest date in Mayan chronology then known. As Captain T. A. Joyce has pointed out, it was owing to his interest in following up rumours of ruined cities in the depths of the tropical forest that attention was directed to the remarkable series of stone buildings which link the temples of Yucatan to the ancient Mayan centres of Guatemala and Honduras. Gann also shared in the work of the British Museum's expedition, of which Captain Joyce was in charge, when the great ruins of Lubaantum, Pusilhà and Minanhà were excavated and explored. An explorer rather than an excavating archæologist, owing mainly to lack of opportunity, Gann was conspicuously generous in placing his knowledge at the services of others whose opportunities were more favourable. His collections enrich both the British Museum and the Liverpool Museum.

In addition to the series of volumes recording his journeys of exploration, and papers in the journals of learned societies, Gann was the author of a number of works dealing with Central American archæology and prehistory, of which the latest was "Mexico from the Earliest Times to the Conquest" (1936). With J. Eric Thompson he also wrote "A History of the Maya" (1931).

Dr. Francis G. Pease

The Mount Wilson Observatory has suffered a severe loss by the death on February 7, at the age of fifty-seven years, of Dr. Francis G. Pease.

For many years Dr. Pease was in charge of instrument design at the Observatory. When the United States declared war in 1917, he became chief draughtsman to the National Research Council, Washington. He gave a great deal of thought to the design of very large telescopes, and his investigations showed that the construction of a 200-in. telescope presented no insuperable difficulties : he has been closely associated with the design of this telescope, which is to be erected on Mount Palomar.

Dr. Pease did a great deal of nebular photography, and many of his beautiful photographs of nebulæ are celebrated. He determined the line-of-sight velocities of a number of the extra-galactic nebulæ and investigated the rotation of some of them. In association with Dr. W. S. Adams, the spectra of various novæ were obtained after the novæ had become faint, and the novæ were shown to have become Wolf-Rayet stars.

Dr. Pease collaborated with Prof. Michelson in the application of the interferometer to the measurement of stellar diameters. With a special interferometer, 20 ft. in length, mounted on the end of the tube of the 100-inch telescope, he succeeded in measuring the angular diameter of Betelgeuse on the night of December 13, 1920, a memorable observation because it was the first measurement of the diameter of a star ever made. The measures of stellar diameters with this interferometer, and afterwards with a specially constructed 50-ft. interferometer telescope, have mostly been made by Dr. Pease. They demanded considerable skill in adjustment and great patience, qualities which Dr. Pease possessed in a unique degree.

When Prof. Michelson repeated the famous Michelson-Morley experiment with a large steel and invar interferometer in the years 1927–29, Dr. Pease collaborated in the observations. The purpose was to investigate the possible ether-drift which D. C. Miller claimed to have established. No displacement of the fringes so great as one fiftieth of that to be expected if such an ether-drift existed was obtained.

Dr. Pease was working with Prof. Michelson on the measurement of the velocity of light, in a pipeline one mile in length evacuated to a pressure of a few millimetres, when Prof. Michelson died in May 1931. This investigation was then placed under the direction of Dr. Pease, who succeeded in holding a pressure of 2–3 mm. in a line built up of 60-ft. sections of steel pipe, 3 ft. in diameter. Multiple reflections from mirrors at the two ends of the pipeline increased the effective length of path. The mean velocity obtained from several sets of measures, comprising in all 2885 determinations, was 299,774 ± 11 km./sec., which must be regarded as the best determination of this velocity. H. S. J.

Prof. Max Neisser

THE death on February 25 of Prof. Max Neisser in his sixty-ninth year creates another blank in that distinguished roll of German bacteriologists who have occupied chairs of hygiene modelled on the Koch tradition. The name of Neisser bulks largely in bacteriological literature. Albert Neisser of Breslau, the discoverer of the gonococcus, was an uncle of Max; and the veriest tiro in bacteriology is, at a very early stage, introduced to at least one achievement of the latter—the Neisser stain for *C. diphtheriæ*.

Born in 1869 at Liegnitz in Silesia, Max Neisser removed with his parents to Berlin, where he received his schooling and his medical training. The work involved in the preparation of his thesis for the doctorate in medicine, which he obtained in 1893, was carried out in Rubner's laboratory. In 1899 he met Paul Ehrlich—a great event in his life. In the same year he went to Frankfort-on-Main, where he was given charge of the department of bacteriology and became a professor in 1901. In 1909 he was appointed director of the new Städtisches Hygienisches Institut, later to be named the Stadtisches Hygienisches Universitats-Institut when the University of Frankfort was founded in 1914.

During the Great War, Neisser did valuable service first in a field dressing station and later as a consultant on hygiene.

When the War ended, Neisser returned to his professorial duties, resumed his scientific work, and took a prominent part in the organization of public hygiene in Frankfort. In April 1933 he retired, at the age of sixty-three years, and has since held the title of professor emeritus.

Since he embarked on his research career forty-five years ago, Neisser has been a most devoted and assiduous student, and his contributions, which cover a surprisingly wide range, embracing bacteriological, immunological and hygienic studies, have been many. Before me is a list of no fewer than 156 titles of contributions by him in the period 1893–1935. Here I can do no more than refer briefly to some of the more outstanding achievements to his credit in the field of bacteriology and immunology.

His sojourn at Breslau under Flugge in the closing years of the nineteenth century gave Neisser an opportunity of studying what was then a very acute and pressing problem, the differentiation of diphtheria bacilli from other diphtheroids, and the elaboration of a working technique for use in institutions concerned with the diagnosis of diphtheria.

The well-known Neisser stain for demonstration of the metachromatic bodies in diphtheria bacilli dates from this period. As one of Ehrlich's band of workers in the Frankfort Institute, Neisser, with his colleague Wechsberg, took a prominent share in those pioneer studies conducted under Ehrlich's guidance on the nature and mode of action of hæmolysins, antitoxins and bactericidins in immune sera during the early years of the present century. The Neisser-Wechsberg phenomenon (1901), which disclosed the fact that excess of immune body in relation to available complement interfered with bactericidal action, was an important outcome of this period of his activity. Its precise mechanism is perhaps not even now elucidated and may have to await progress in the physicochemical attack now being made on the nature of antigen-antibody combinations.

Neisser devoted much attention to the elaboration of accurate plating technique for evaluating bactericidal action, and in connexion with the staphylococcus, on which he wrote widely, he explored with Wechsberg the possibility of detecting by aid of methylene blue the killing power of staphylococcal leucocidin on leucocyte suspensions (so-called bioscopic method).

In 1903 Neisser's demonstration of the fact that influenza bacilli can be grown on ordinary agar in symbiosis with *B. xerosis* is of considerable historical interest in the light of later developments in our knowledge of the essential growth factors of the hæmophilic group of organisms.

In 1906 a most interesting and fruitful field in bacterial variation was opened up by Neisser's observations on an organism (*B. coli mutabile*) which, when grown on lactose-agar, was capable of throwing off variants endowed with the power of fermenting lactose. The analysis of this 'mutation' phenomenon, pursued by Massini and Reiner Muller and particularly by Penfold in Great Britain, added much to our knowledge of variation phenomena in bacteria, in so far as their fermentative properties are concerned.

During the period of his directorship of the Hygienic Institute (1909–33), Neisser's activities, so far as one may judge from the titles of his numerous papers, were, for the most part, bound up with problems of public hygiene over which he freely ranged, the care of the tuberculous, milk provision, bacteriological water analysis, disinfection and water purification being particularly favoured subjects. In the later years of his directorship he devoted much attention to the possibilities of water purification by employing the bactericidal action of silver ions.

There can be no doubt that Max Neisser was an unusually gifted and versatile occupant of the first Frankfort chair of hygiene, beloved of his students and ever ready to spend himself freely in furthering every project likely to raise the standard of public hygiene in the city of his adoption. J. C. G. LEDINGHAM.

Dr. Gilbert Slater

We regret to record the death of Dr. Gilbert Slater, the economist and an authority on the culture and village life of southern India as it existed twenty years ago, which took place at Oxford on March 8 at the age of seventy-three years.

Slater was born in Plymouth on August 27, 1864, the son of Daniel Slater, a schoolmaster. A member of St. John's College, Cambridge, he was also a D.Sc. in Economics of the University of London, a degree to which, however, he was admitted so late as 1905. After leaving Cambridge he was for a time a schoolmaster; but he left the profession to take up lecturing, social work and political activities. In 1905 he was elected the first Labour mayor of Woolwich. The publication of his doctor's thesis in enlarged book form under the title "The English Peasantry and the enclosure of Common Fields" (1907) led to his appointment as head of Ruskin College, Oxford, in 1909. Here he remained until 1915, when he accepted the newly founded chair of Indian economics at the University of Madras. In 1921 he became publicity officer for Madras and a member of the Legislative Council. Slater returned to England in the following year, and in addition to lecturing at the London School of Economics and to Indian Civil Service students at Oxford, wrote a number of books on social and economic subjects, among which may be mentioned "The Growth of Modern England" (1932) and a final work on India, "Southern India, its Political and Economic Problems" (1936), as well as a chapter on the social and industrial history of Kent in the Victoria County History.

Of Slater's more active years, viewed in relation to scientific thought, the period which he spent in India was the most productive and influential. "Some South Indian Villages" (1917), which he edited, was based on surveys made by his students, whom he sent out with a questionnaire of his own devising to make first-hand observations of conditions in the villages with which each was well acquainted by residence. These intensive studies produced a mass of ethnographic and economic data, variable in quality, it is true, but of very considerable value. In the final form given by the editor, this report has had a profound effect on subsequent Indian political and sociological theory and practice. His analytical faculty also turned to the study of Indian culture and in his "The Dravidian Element in Indian Culture", published in 1923 after his return to England, he gave an orientation to the study of the place of the Dravidians in the development of Indian civilization, which, like his work on the Indian village in its special field, has greatly influenced the development of later Indian studies, although in directing attention to and emphasizing the affinities of the Dravidian and Mediterranean peoples, he was developing ideas already adumbrated by Mr. F. J. Richards, as Dr. A. C. Haddon has pointed out (see "The Races of Man", by A. C. Haddon, 1924, p. 150, where Slater is, curiously, miscalled "Scott").

Mr. F. J. Hanbury

Mr. F. J. Hanbury, who died on March 1 at the age of eighty-six years, was the son of Cornelius Hanbury, of the firm of Messrs. Allen and Hanbury, wholesale druggists. He was educated at the Friends' School, Tottenham, and afterwards studied pharmacy, passing with honours the two examinations of the Pharmaceutical Society. He joined his father's business in 1872, becoming a partner and eventually chairman of the firm in 1916.

In the 'eighties Mr. Hanbury formed a friendship with the late Rev. E. S. Marshall and became interested in British flowering plants. The two explored the northern Scottish Highlands together, and Hanbury began a study of the difficult genus *Hieracium*. Of this group he described several new species, and in 1889 published the first instalment of a sumptuously illustrated monograph. Before this work had proceeded far, however, it was found impracticable to continue it in the manner contemplated, and it was abandoned. Mr. Hanbury then turned his energies to the production of a flora of Kent, with Marshall as collaborator, and this was completed and published in 1899.

From this date Hanbury did little further botanical work, but he continued to act as editor of the "London Catalogue of British Plants". For some time he took a keen interest in entomology, but after his removal to East Grinstead he devoted himself to the development of his magnificent garden and the cultivation of tropical orchids. He was a prominent member of the Royal Horticultural Society, serving on the scientific and other committees, and was a recipient of the Society's Victoria Medal of Honour. He was almost the 'father' of the Linnean Society, which he had joined in 1873. He recently presented to the Botanical Department of the British Museum (Natural History) the important herbarium of Dr. Boswell Syme, which he had acquired many years previously.

H. W. PUGSLEY.

We regret to announce the following deaths:

Prof. J. E. Coover, emeritus professor of psychology in Stanford University, on February 19, aged sixty-five years.

Sir Raymond Crawfurd, registrar of the Royal College of Physicians of London, known for his work on the history of medicine, on March 9, aged seventy-two years.

Sir Reginald Fleming Johnston, K.C.M.G., C.B.E., formerly commissioner for Wei-hai-wei, an authority on the Chinese language and people, on March 6, aged sixty-four years.

Major A. D. Lumb, of the Scientific and Technical Department of the Imperial Institute, known for his work on the geology and mineral survey of southern Nigeria and the Udi Okana coalfield.

Prof. A. Magnan, professor of animal mechanics applied to aviation in the Collège de France, aged fifty-seven years.

Mr. Melville Hilton-Simpson, the distinguished traveller and ethnologist, on March 17, aged fifty-seven years.

News and Views

New Fellows of the Royal Society

AT the annual election of fellows of the Royal Society held on March 17, the following were elected: G. D. Bengough, consultant to the Chemical Research Laboratory, Department of Scientific and Industrial Research; C. H. Best, professor of physiology, University of Toronto; W. Brown, professor of plant pathology, Imperial College of Science and Technology; J. W. Cook, professor of chemistry, The Research Institute, Royal Cancer Hospital; T. L. Eckersley, research physicist, Marconi's Wireless Telegraph Co.; G. I. Finch, professor of applied physical chemistry, Imperial College of Science and Technology; W. E. Gye, director of the laboratories of the Imperial Cancer Research Fund; W. V. D. Hodge, Lowndean professor of astronomy and geometry, University of Cambridge; J. S. Huxley, secretary of the Zoological Society of London; J. Jackson, H.M. Astronomer at the Cape; Sir Robert Mond, chemist and Egyptologist; J. E. Richey, district surveyor, H.M. Geological Survey; F. S. Russell, naturalist at the Marine Biological Association; B. F. J. Schonland, professor of physics, University of Cape Town; F. S. Sinnatt, director of fuel research, Department of Scientific and Industrial Research; K. M. Smith, senior research assistant, Plant Virus Station, Cambridge; E. Stedman, lecturer in the Department of Chemistry in relation to Medicine, University of Edinburgh; C. E. Tilley, professor of mineralogy and petrology, University of Cambridge; W. E. S. Turner, professor of glass technology, University of Sheffield; H. H. Woollard, professor of anatomy, University College, London.

Presentation to Sir Arthur Harden

AT the annual general meeting of the Biochemical Society held on March 11, a presentation was made by the Society to Sir Arthur Harden, on the occasion of his retirement from the editorship of the *Biochemical Journal*. The presentation took the form of an inscribed salver, bearing the signatures of all those still living who have served on the Committee of the Society during the twenty-five years of Sir Arthur's editorship. In making the presentation on behalf of the Society, the present chairman of committee, Prof. H. J. Channon, recalled the early history of the *Biochemical Journal*. Founded by Prof. Benjamin Moore and Mr. E. Whitley in 1906, it was first issued as a private venture from the Department of Biochemistry in the University of Liverpool. In 1911, at the instance of Dr. (now Prof.) R. H. A. Plimmer and Mr. J. A. Gardner, there was formed an organization of biochemists, called at first the Biochemical Club, the members of which soon came to feel the need for a journal to cover the widest interests of the growing science of biochemistry in Great Britain; negotiations were therefore started which led, in October 1912, to the acquisition of the *Biochemical Journal* by the Biochemical Club, which at the same time changed its designation to Biochemical Society; the editors appointed by the newly formed Society were Arthur Harden and William Bayliss. Prof. Channon traced the remarkable growth of the *Biochemical Journal* from its modest beginning to its present position as one of the outstanding biochemical publications of the world, and in thanking Sir Arthur for his great services to the Society he paid an eloquent tribute to his qualities as an editor.

IN supporting Prof. Channon, Sir Frederick Gowland Hopkins emphasized the importance of Sir Arthur Harden's own work in influencing the development of biochemistry in Great Britain, and the advantage which had accrued to that science in its early days from the entry into it of an accomplished chemist. Sir Frederick referred to the sacrifice of time involved for an active investigator in editing a scientific journal; but pointed out that, regrettable as such loss of time might be, it was only an active investigator who could give full and sympathetic understanding to the difficulties of his colleagues in presenting the results of their researches; such understanding Sir Arthur had always given in full measure. Sir Arthur Harden, in acknowledging the presentation, expressed his appreciation of the help which he had received from his various co-editors. Sir Arthur stated his conviction of the importance of free and reasonably detailed publication of results in the development of a growing science such as biochemistry and indicated the way in which as an editor he had attempted to give effect to this conviction. The occasion of the presentation constituted something of a landmark in the history of biochemical publications in Great Britain since the increasing size of the *Biochemical Journal* has necessitated a further subdivision of the editorial work. It will be hoped by all who are interested in the progress of biochemistry that it will be possible under the new arrangements to maintain the high standard which has been reached as the result of Sir Arthur Harden's work during the past twenty-five years.

Dr. W. H. Pearsall

DR. W. H. PEARSALL, whose appointment to the chair of botany at Sheffield has recently been announced, was educated at Ulverston Grammar School and the University of Manchester, where he continued his studies after graduation. In 1921 he was awarded the D.Sc. for his work on the aquatic vegetation of the English Lakes. During the Great War he served with a battery of the Royal Garrison Artillery and later with the Royal Engineers. He joined the staff of the Botany Department at the University of Leeds in 1919 and was appointed reader in 1922. Dr. Pearsall has taken an active part in many scientific societies; he acted as secretary to the Society for Experimental Biologists in 1928–33, and has just completed his term of office as president of the British Ecological Society; this year he has also taken over the editorship of the *Journal of Ecology* from Prof. A. G. Tansley. He acted as joint secretary of the Yorkshire Naturalists' Union with the late Mr. F. A. Mason in 1919–29 and since 1933 has been co-editor of *The Naturalist* with Mr. W. R. Grist; in 1937 he served as president of the Union. From 1931 until 1937 Dr. Pearsall acted as honorary director of the Freshwater Biological Station at Wray Castle, Windermere, where he has taken an active part in organizing most successful short courses in freshwater biology for senior university students; his guidance has also been of great value to a series of investigators, who have studied problems of freshwater biology at this centre.

DR. PEARSALL's published scientific work has been mainly upon problems of ecology and upon various aspects of the physiology of growth in plants, with especial reference to problems of nitrogen nutrition. His work, with which his father was associated at its inception, upon the freshwater biology of the English Lakes, is very widely known. It has provided an admirable basis for many of the more intensive investigations that can now be attempted with the establishment of a permanent centre of investigation upon Lake Windermere. Dr. Pearsall's interests in ecology have ranged very widely; his recent presidential address to the British Ecological Society dealt especially with soil factors in relation to plant distribution. The importance of the oxidation-reduction potential is stressed, and Dr. Misra under his guidance has recently shown the significance of this factor in connexion with the mud deposits in the Lakes. Dr. Pearsall's studies upon plant metabolism have been linked up with his extensive studies of the growth of algæ, especially *Chlorella*, in pure cultures. This work has been extended recently with the aid of a grant from the Leverhulme Fund, but already many studies of plant metabolism have been published by Dr. Pearsall and his students in the last few years, including (with Dr. M. C. Billimoria) some very suggestive notes upon nitrogen loss from plants.

Atlantic Meteorology and Trans-Atlantic Flight

MR. F. ENTWISTLE, head of the Overseas Division of the Meteorological Office, Air Ministry, delivered the Symons Memorial Lecture before the Royal Meteorological Society on March 16, taking as his subject, "Atlantic Flight and its bearings on Meteorology". Mr. Entwistle stated that the success of the flights across the North Atlantic last year by Imperial Airways, Ltd., in conjunction with Pan American Airways, Inc., was due in very large measure to the thorough preparations which preceded them and to the ground organization, including radio and meteorological services, which was provided. The preliminary investigations carried out by the Overseas Division of the Meteorological Office in order to provide essential operational data before the flights commenced were described. The first investigation, commenced early in 1936, had as its object the determination of the maximum average head wind component that would be experienced on an east to west track along the great circle route between Ireland and Newfoundland. The results, which were based on an examination of data covering a period of ten years, indicated that while the maximum wind speed likely to be encountered at any point was 95 m.p.h., the maximum average speed over the whole route was 60 m.p.h. This average speed, however, occurred only once in ten years, and if, in the operation of a trans-Atlantic aircraft, an allowance was made for a maximum head wind on the east–west track of 40 m.p.h., there would be very few occasions in any one year when it was necessary to cancel the flight. A more comprehensive investigation followed in which the times of flight of aircraft of different air speeds on alternative trans-Atlantic routes were compared.

LATER investigations were concerned with the meteorological conditions affecting the operation of aircraft in Newfoundland, the variation of wind with altitude over the North Atlantic and the frequency and minimum heights of low cloud. For one year from November 1936 a technical officer of the Overseas Division of the Meteorological Office was attached to the *Manchester Port*, a cargo ship operating between Manchester and Canada. He completed eight round voyages, in the course of which he made regular pilot balloon observations to determine the wind speed and direction at different altitudes, constructed daily weather charts from observations received by radio from Europe and North America as well as from ships at sea, and studied in detail the characteristics of the Atlantic disturbances through which the ship passed. These investigations, which are essential to the supply of accurate meteorological information for trans-Atlantic flying, will benefit meteorological science generally and, in particular, the weather forecasting services of the countries of western Europe, the greater part of the weather of these countries developing over, and moving from, the Atlantic. The development of long-distance air routes in various parts of the world is stimulating similar meteorological activity and is providing data for investigation on a scale hitherto unknown.

Air-Raids on Barcelona

LAST week in the House of Commons, Mr. Chamberlain expressed his own and indeed the general view of the recent air-raids on Barcelona when he said that no one could read the reports "without horror and disgust". This feeling must be aroused by the whole practice of bombing from aircraft, especially from great heights, for it is inevitable that there should be loss of many innocent lives and destruction of buildings of no military significance such as universities and scientific and other learned institutions. In this connexion we have received a copy of the following cable from the "Subsecretario Instruccion Publica" addressed to the president of the Royal Society of Medicine: "The Regular Air Force of Germany and Italy is demolishing the cities of Spain. The University of Barcelona like the Cajal Institute in Madrid has been almost completely destroyed. The same has happened to other centres of culture. During the last three days of terrible and continuous bombing, more than a thousand people were killed in Barcelona alone. We Spaniards of liberal and democratic convictions who only devote ourselves to literary and scientific activities protest against these monstrous crimes. At the same time we appeal to the sensitivity of our English colleagues and ask for their help in the defence of the independence of our country as well as of the universal principles of humanity, justice and law which the Spanish Republic implies. We ask you to bring to bear all your influence on the British Government so that it may take steps to avoid these barbarous atrocities, which are directed not only against defenceless human beings but also against the civilization and peace of the world. Jacinto Benavente (Nobel Prize); Ignacio Bolivar (naturalist); Pio Del Rio Hortega (biologue); P. Bosch Gimpera (archeologue); Enrique Moles, D.Sc.; Jose Xirau, D.L.; A. Duperier, D.Sc."

Exhibition of British Archæology

THE exhibition illustrating finds in Britain and Northern Ireland in the course of archæological exploration during the last five years at the Institute of Archæology of the University of London, Regent's Park, London, which was opened by Sir Charles Peers on March 21, is unique and the occasion historic. No exhibition of the kind has been held before, nor has so widely varied a collection of archæological material been assembled for temporary exhibition previously. Considering the relatively brief period during which the work of excavation has been carried out, the exhibition shows a remarkable and healthy activity in practical archæological study in Great Britain such as, it is probable, could not be parallelled elsewhere. The area covered includes England, Scotland, Wales and Northern Ireland, and the exhibits are drawn from sites in more than thirty counties. In time they range from the pre-glacial industries of East Anglia to Stuart pottery from the ditch of the Tower of London, lent by the Office of Works. Among the sites of major importance represented are Verulamium, of which the close of excavation just comes within the period, Miss Kenyon's excavations at the Old Jewry Wall of Leicester, with its evidence of Belgic occupation, and Dr. R. E. Mortimer Wheeler's exploration of Maiden Castle, with the interesting evidence of cannibalism and the remains of the last defenders of the fortress in A.D. 43. Material which should prove of intense popular interest is that from Castle Dore in Cornwall, which removes King Mark, father of Iseult, from the category of legendary figures and makes him a historical personage. Recent activities in, and discoveries by, air photography are well displayed. The exhibition will remain open daily from 11 a.m. to 4 p.m. until May 2.

Electron Diffraction and Surface Structure

IN opening the discussion on electron diffraction and surface structure before a joint meeting of the Physical and Chemical Societies held on March 17, Prof. G. I. Finch compared electron diffraction with other methods of surface structure examination, and cited cases where the microscope or X-rays may give a wrong impression of the structure of deposits and of the size, shape and chemical nature of thin crystalline films. He described, among others, a striking experiment on the orientation of fatty acids by friction, which seems to have a direct bearing on the nature of the mechanism of lubrication. Thus the previously unorientated molecules in a stearic acid layer deposited on a metal surface can be made to point in a common direction by rubbing. If the surface be rubbed in all manner of ways, it is the last stroke only which determines the final direction of orientation of the stearic acid chains. Prof. Finch also gave an account of new experiments which confirm the conclusions previously arrived at by electron diffraction as to the structure of the polish layer on calcite. Sodium nitrate crystals were found to orientate in such a way as virtually to continue the structure of calcite when deposited on the polish layer on a cleavage face and which electron diffraction had shown to be of single crystal structure integral with the main crystal. A calcite surface cut and polished in such a manner as to be steeply inclined to all cleavage planes, however, gives a halo pattern characteristic of an amorphous layer, and on such a surface the nitrate crystals do not orientate but point in all directions just as they do when grown, for example, on a glass surface. After heating, which causes this amorphous polish layer to recrystallize, the sodium nitrate crystals orientate once more.

The Fulham Power Station

THE Institutions of Civil Engineers and Electrical Engineers had a joint meeting on March 22 to discuss the new Fulham Power Station, which when complete will be the largest municipally owned base-load station in the British Isles. The station lies east and west, with the boiler house on the east, and is situated 60 ft. from the river frontage along the west bank of the Thames from Wandsworth Bridge. The first half of the paper was written by J. F. Hay and describes the constructional work, and the second half, by W. C. Parker and H. Clarke, discusses mechanical and electrical considerations. A point which has come prominently forward during recent years is the necessity of having as wide a specification as possible for the coal used. The effect of having two of the base-load stations on the Thames equipped with the same kind of stoker and similar methods of feeding is making a considerable demand for a special type of coal from the coalfields, and this both increases the price of this type of coal and brings about a shortage of supply for it. The Ministry of Health requires constant tests to be made of the sulphur content of the flue gases, but the difficulty of doing this, even when working to so low a sulphur content as 0·006 grain per cubic foot, was overcome by means of a new recording device. Continuous tests of the sulphur activity in various parts of London since April 1, 1936, prove that the starting of the Fulham Power Station on November 1, 1936, has had no apparent effect on the atmospheric pollution. The pollution varies with the season and with the weather, being large in winter and during cold winds. The two chimneys are built of reinforced concrete and rise 300 ft. above ground-level. The gas-washing plant runs on a non-effluent system which is similar to that devised concurrently by Imperial Chemical Industries, Ltd.

Science and Socialism

THE first of a "Social Science Series" of pamphlets edited by W. P. Dreaper is entitled "The Future of Civilisation and Social Science" (London: E. T. Heron and Co., Ltd. 1*s*.). In it Mr. Dreaper presents a study of the principles of scientific meliorism based on Jane Hume Clapperton's book published in 1885, in which socialism is defined as concerted aims for social ends, and scientific meliorism may be regarded as a form of socialism under which progress must come through the individual social unit and not by means of social veneer. Scientific meliorism discriminates between benevolence which is beneficial and that which is not, giving no support to charities which injure the independence of the poor, or relieve them of parental responsibility. It opposes the social forces of sympathetic selection which result in the survival of the unfit and seeks to promote intelligent selection which would result in the birth of the fit. It strenuously supports co-operation in industry as a means of progress and harmony of interests, and proper distribution as a means of improving human conditions. Scientific meliorism also advocates a rational treatment of crime, in which vindictiveness has no ultimate place, and calls for a similar rational attitude to such questions as manners, dress, the equality and relations of the sexes, marriage laws, laws of inheritance, etc., the regulation of population in relation to the natural and industrial position of a nation, and Mr. Dreaper briefly discusses the bearing of its principles on the study of international problems.

Developments in Storage Batteries

DURING last year, there has been a widespread increase in the number and the variety of the applications of batteries for stand-by purposes and emergency lighting. In the annual review number of the *Electrician* of January 28, Mr. E. C. McKinnon points out that this is partly due to air-raid precautions, which naturally trust to storage batteries for emergency lighting. Manufacturers are using the popular sizes of the starting batteries used in motor-cars for this purpose when circumstances permit. In other cases, alkaline batteries or sealed-in lead-acid accumulators are employed. The vast programme for broadcasting and recording the incidents of the Coronation ceremony and processions was largely dependent upon batteries. Car radio equipment has been applied to police patrol cars and to police patrol pedal-cycles. Many systems of battery-controlled fire alarms have also been installed. There has been a considerable increase in the demand for accumulators for deaf-aid equipment.

VERY small batteries have been developed for use in meteorological balloons. These are made up into low-tension cells weighing 1 oz. each, and 60 cell (144 volts) high-tension batteries weighing only 9 oz. when complete with electrolyte. There has been a great demand for batteries for auxiliary propulsion of trolley buses. This system is most useful for manœuvring the vehicles at termini or at special points such as football grounds or on the route lines in the event of power supply failure. There has been an increase in the number of electric vehicles in operation last year of 31 per cent. Bakeries, dairies and salvage departments are using large fleets of electric vehicles. Fleets of 100 to 150 electric vehicles are now not uncommon. Air conditioning by the aid of storage batteries has made great progress in India, but the need for it in Great Britain is not large at present. There have been more than a hundred patents in connexion with accumulators applied for last year, but none of them proposes any radical change in design. Special batteries are much used in aeroplanes and submarines. The standardization of accumulators is receiving attention both in Great Britain and internationally.

Journal of Marine Research

DURING the past several years there has been increasing interest in oceanographic research in the United States, which led to the foundation of the Woods Hole Oceanographic Institute and a special department of the University of Washington, both with well-equipped vessels. From these, and the already established laboratories, there has come very real contributions to our knowledge of the oceans—the nature and causes of the current systems on one hand, and, on the other, studies in the varying productivity of the waters in plant and animal life. It is gratifying that Great Britain is now engaging in active co-operation with the Woods Hole Institute in a survey of the fluctuations from year to year in the current system of the north-west Atlantic, for which the Royal Society is now fitting out a vessel. The annual crop of scientific papers dealing with oceanography has grown rapidly. American contributions appear in rather many and diverse journals, both American and European, so the birth in November last of the *Journal of Marine Research* comes at a time when its growth is likely to be rapid. It is published by the Sears Foundation, Oceanographic Laboratory of Yale University, and its scope includes articles on physical meteorological theory, owing to the "intimate connection between hydrospheric and atmospheric events in nature, and to the virtual identity of dynamic methods and theory in Meteorology and Oceanography". The six contributions appearing in the first number are equally divided between physical and biological subjects, and include an article on evaporation from the oceans by H. U. Sverdrup, now director of the Scripps Institute, on seasonal variations in the water of San Juan Channel, and on a survey off the mouth of the Mississippi, showing effects of river water and the distribution of phytoplankton.

Medical Milestones

UNDER this heading, the *Medical Record* of New York for January 5 mentions the following notable events in the history of medicine which occurred in the course of 1838: foundation of the University of Messina, which later developed a remarkable medical curriculum, and of the Medical College of Richmond, Virginia; publication by Malgaigne of his treatise on experimental surgery and by Johannes Müller of his treatise on tumours; the first accurate description of pulmonary tuberculosis by Corrigan; performance by Mettauer of the first operation for vesico-vaginal fistula; description by Southwood Smith of conditions, especially fevers, among the poor in London in his reports to Parliament, and the foundation of the Royal Orthopædic Hospital of London.

Anti-Rabic Treatment in Southern India

THE director, Major Iyengar, in his annual report for 1936 of the work of the Pasteur Institute of Southern India, Coonoor, states that 493 patients underwent a full course of treatment, an increase of 60 compared with the previous year. For the fourth time during the thirty years of its existence, no deaths occurred from hydrophobia among those treated at the Institute. In addition to the treatment at the Institute, 15,302 courses of anti-rabic vaccine were issued for use at out-centres. Semple's carbolized sheep vaccine was in use, prepared from Paris fixed virus, which was in its 978th passage at the close of the year. In addition to human beings, 659 animals also received anti-rabic treatment during the year.

The Day Lily

MEMBERS of the genus *Hemerocallis* enjoy an increasing popularity as garden plants. The name signifies 'beauty for a day', and is a reliable description for individual flowers. The plant, however, maintains a succession of bloom, and is tolerant of a wide variety of cultural conditions. Mr. G. P. Baker has prepared a short monograph of the genus (*J. Roy. Hort. Soc.*, 62, 9, 399–411, Sept. 1937). A historical summary traces the early references to *Hemerocallis flava* from the time of Dioscorides, whilst the modern uses of the plant as medicine and as a flavouring in China, are set forth. Detailed descriptions of fourteen species and their variants impart much knowledge for the gardener.

Société des Amis de Paul Painlevé

THE late Paul Painlevé made a place for himself in contemporary history not only as a great mathematician but also as a statesman of conspicuous ability. A collection of his essays and speeches are gathered together in book form (price 20 francs), and published by the "Société des Amis de Paul Painlevé", which has for its aims the cultivation of his memory and of his scientific and democratic ideals, and eventually the publication of his papers. This association has issued an appeal to all the friends of Painlevé throughout the world, and will particularly welcome adherents from Great Britain (minimum subscription, 1*s*. 6*d*. a year). The chairman of this organization is M. Pierre Appell (3 rue du Vieux Colombier, Paris), who was one of the closest collaborators of the great French statesman.

Medical Men in Austria

WE have received the following communication from the Medical Peace Mission, 12 Kent Terrace, Park Road, London, N.W.1, signed by eighteen distinguished British medical men: "In view of recent events, we desire to express our alarm at the possible fate of our colleagues in Austria. There are in that country many revered physicians and surgeons who are likely to fall into disfavour with the National Socialist Government either on account of their medical or social views or on account of their belonging to the Jewish race. Judging from what has happened in Germany in the past, we are afraid that serious discrimination will be exercised against them and that even the chance to leave a country which is no longer hospitable to them may be refused. We beg our colleagues in all countries to watch the progress of events with the closest attention and to do all in their power, whether by public protest or by public or private assistance, to stand by any members of our profession who may suffer hardship under the new régime."

The Night Sky in April

Full moon occurs on April 14 at $18\cdot3^{h}$ and new moon on April 30 at $5\cdot5^{h}$ U.T. No stars brighter than mag. 6·1 are occulted during the month; for particulars of the seven occultations visible from Greenwich, see page 526 of the "Nautical Almanac". Lunar conjunctions with the planets occur as follows: on April 1^{d} 23^{h} with Venus: April 2^{d} 6^{h} with Mercury: April 3^{d} 8^{h} with Mars: April 25^{d} 2^{h} with Jupiter and April 28^{d} 11^{h} with Saturn. On April 8^{d} 16^{h}, Mercury and Venus are in conjunction, and on April 15^{d} 20^{h} Venus and Uranus, Venus being only 0·1° north of Uranus (geocentric positions). Venus and Mars are both evening stars; Mercury is an evening star until April 21, and at greatest eastern elongation on April 2. On April 1 at about 19^{h}, the moon's slender crescent and the planet Venus will be nearly at the same altitude low in the western sky. In mid-April at 22^{h}, Orion will have nearly set in the west, but Procyon, Castor and Pollux still remain. Capella in the north-west balances Vega in the north-east. The bright star Arcturus, the spectrum of which closely resembles that of sunspots, is conspicuous east of the meridian. Arcturus has the notable proper motion of 2·3″ per annum. In its train, there is the small, beautiful constellation of Corona Borealis. On or about April 21, the Lyrid meteors may be looked for, their radiant point being at R.A. 18^h 4^m and Dec. 33° N. It should be noted that Summer Time in the British Isles commences on Sunday, April 10, at 2^h.

Announcements

PROF. F. G. DONNAN has been elected an honorary member of the Verein Osterreichischer Chemiker.

SIR ROBERT HADFIELD has been awarded the Trasenster Medal and Diploma for 1938 by the Association des Ingénieurs de Liège. This award has previously been given to M. Henry Le Chatelier, the well-known French man of science, the Marchese Marconi, M. Edouard Branly, the distinguished physicist and one of the pioneers of wireless, M. Georges Claude, inventor of the processes known under his name for the liquefaction of air and for the fixation of atmospheric nitrogen, Mr. Waldemar Lindgren, American geologist, and M. André Blondel, distinguished for his researches in electricity and illumination.

THE London Midland and Scottish Railway has appointed Dr. W. A. Macfarlane to be senior research chemist. Dr. Macfarlane was educated at Westminster School and Balliol College, Oxford ; he took a first in chemistry in 1930, and was awarded a B.Sc. for his research work in physical chemistry. He acted as demonstrator in natural science at Balliol from 1930 until 1932, and was then elected a Commonwealth Fund fellow at the University of California, where he carried out research in spectroscopy. Since 1934 he has been a scientific officer at the Fuel Research Station, where he specialized on the production of synthetic oils, and later acted as personal assistant to the Director of Fuel Research.

MR. F. H. Wynne, deputy chief inspector of mines, has been appointed chief inspector of mines in succession to Sir Henry Walker. Sir Henry Walker, who entered the Mines Inspectorate in 1902 and has been chief inspector for nearly fourteen years, retired on March 17 on reaching the age limit.

THE sixth of a series of public lectures on "Science in the Social World", which has been organized by the Left Book Club Scientists' Group, will be held on March 28, at 8 p.m. at the Conway Hall, Red Lion Square, W.C.1, when Prof. P. M. S. Blackett will speak on "The Social Background of the Rise of Science in the Seventeenth Century".

DR. H. H. VÖLCKERS, Plenipotentiary Minister of the German Reich at Havana, has been elected an honorary member of the Cuban Society of Biology, and Dr. Hans Boker, professor of anatomy at Jena, an honorary member of the Cuban Society of Natural History.

DR. FRIEDRICH BERGIUS has been made an honorary member of the Physical Association at Frankfort, and Dr. Eduard Richters, senior veterinarian in the Army Veterinary Investigation Department, a member of the Imperial Leopold Caroline German Academy at Halle.

AN anti-alcohol museum at Warsaw has recently been opened by the Polish Minister of Social Welfare.

THE eighth International Congress of Thalassotherapy will be held at Montpellier on June 3–5 under the presidency of Dr. A. Aimes, when papers will be read on the meteorological factors of sea climate. Further information can be obtained from the general secretary, 8 rue André-Michel, Montpellier.

The annual Conference of the Museums Association will be held in Belfast on July 4–9, under the presidency of Dr. R. E. Mortimer Wheeler. Further information can be obtained from the Secretary, Museums Association, Chaucer House, Malet Place, London, W.C.1.

THE Chicago Tumor Institute, which is a non-profit-making corporation at 21 West Elm Street, Chicago, was opened on Monday last, March 21. The scientific committee consists of Dr. Max Cutler (director), Sir G. Lenthal Cheatle, Dr. Henri Coutard, Dr. Arthur H. Compton and Dr. Ludvig Hektoen. The Institute will offer consultation service to physicians in the diagnosis and treatment of cancer and radiation facilities for cancer patients. It is also proposed to conduct research at the Institute and to offer training to physicians who may wish to qualify as specialists in the study and treatment of this disease.

THE Cambridge University Press announces two developments in its policy of providing the increasing number of readers not engaged in science, but interested in the advance of knowledge, with informative books by men who are authorities in their own subjects. The first is Einstein's own account of his great discovery of relativity, "The Evolution of Physics", by himself and Dr. L. Infeld, which on March 28 will inaugurate a new series, "The Cambridge Library of Modern Science". Later in the same week will come the first number of a new series of *Discovery*, the popular scientific monthly, which has been taken over by the Cambridge University Press and will provide the general reader with a regular link with the latest discoveries and developments in all branches of knowledge. Dr. C. P. Snow, of Christ's College, is the new editor of *Discovery* and also general editor of "The Cambridge Library of Modern Science".

ERRATUM. In NATURE of March 12, p. 471, letter by Dr. P. Suomalainen entitled "Magnesium and Calcium Content of Hedgehog Serum during Hibernation", par. 4, line 6, for "Kursiv" read "*Helix*".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 559.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Rate of an Atomic Clock in Motion

ACCORDING to the theory of the relation between matter and the luminiferous ether, as developed by Larmor and Lorentz, a moving clock should assume the rate

$$\nu = \nu_0 \sqrt{1 - \frac{V^2}{c^2}},$$

where ν_0 is the stationary rate, V the measured velocity of the clock with respect to the observer, and c the velocity of light.

It was pointed out by Einstein in 1907 that the newly discovered Doppler effect in canal rays offered a means for making a test of this prediction. This experimental test, the crucial nature of which has been emphasized repeatedly in the last thirty years (under the designation of the 'transverse Doppler effect') has not heretofore been performed. It has been commonly considered as beyond experimental practicability, chiefly on the ground that as the moving canal rays are not homogeneous in velocity, the 'displaced' line is too diffuse for sufficiently exact measurement.

This objection has recently been removed, due to the development, by Dempster, of a design of canal ray tube which gives displaced lines of a sharpness comparable with the undisplaced. In this form of tube, the positive ions produced behind the electrode are accelerated between two slightly separated pierced plates between which a high potential difference exists.

Recently, with the assistance of Mr. G. R. Stilwell, I have made an experimental test of the Larmor-Lorentz prediction, using canal ray tubes of the Dempster type. The hydrogen line 4861 A. has been used, observations being made by means of a plane grating of metal on glass of 15,000 lines to the inch, made by Prof. R. W. Wood, which, in conjunction with two 5-in. diameter, 5-ft. focus telescope objectives, formed a sufficiently powerful spectrograph for the purpose. By means of a small concave mirror mounted on the pierced electrodes, end-on observation gave, on one plate, the displaced lines due to motion toward and away from the spectrograph slit. The apparatus was arranged to turn in any desired direction in the horizontal plane.

For the voltages used, which were about 18,000, the displaced H_2 lines, which were the most feasible for study, should, according to the theory, have their common centre of gravity displaced, with respect to the undisplaced line, by approximately 0·05 A. towards the red, which is readily detectable with the dispersion employed.

The result of the experiment was to show a displacement in the predicted direction, independent of the orientation of the apparatus, and agreeing, within the errors of measurement, with the value indicated by theory.

The importance of this experiment lies in the fact that it yields a positive effect, as distinct from the null effects obtained in other optical experiments, which latter might be explained by an entrained ether. It is therefore decisive in favour of the Larmor-Lorentz theory.

A full account of the experiment will be published shortly.

Effect of Solvents on the Absorption Spectrum of Vitamin A

IT has long been known that some substances, for example, indigo, yield variously coloured solutions in different solvents. Change of solvent may affect the intensity and position of absorption maxima in the ultra-violet as well as in the visible spectrum. The fact that this phenomenon has been observed with a related substance, carotene, makes it the stranger that various solvents are commonly accepted as interchangeable for the spectrophotometric assay of vitamin A. Thus ethyl alcohol and cyclohexane received equal sanction at the 1934 International Vitamin Conference and in the 1936 "Addendum to the British Pharmacopœia"; ether is also used in some laboratories, but chlorinated solvents, particularly chloroform, have been regarded with suspicion.

We now find that the vitamin A absorption bands of fish-liver oils and concentrates may vary somewhat with change of solvent, both in position and in magnitude. The values of $E^{1\%}_{1\text{cm}}$ 328 mμ, for three oils and two concentrates, in five solvents are summarized in the accompanying table. For ease of comparison, the values in solvents other than alcohol are expressed as percentages of the absorption in alcohol. Each figure represents the mean of two to four highly concordant independent determinations. Consistently higher results were obtained with alcohol than with cyclohexane or hexane as solvent, and we believe that the differences have real significance.

Substance	$E^{1\%}_{1\text{cm}}$ 328 mμ in alcohol	Absorption at 328 mμ relative to 100 for alcohol				
		Alcohol	Cyclohexane	Hexane	Ether	Chloroform
Halibut-liver oil 12/186	40·8	100	99	102	110	93
Halibut-liver oil 12/214	30·1	100			116·5	93·5*
Fish-liver oil 11/323	52·7	100	97	95	90·5	85·5
Concentrate 12/099	630	100	99	96·5	105	86·5
Concentrate 12/168	480	100	95·5	97	106	86
Average		100	97·5	97·5	107·5	89

* One determination only.

The high results in ether (4 samples out of 5) and the even more markedly low results in chloroform certainly differ from those in alcohol by amounts well outside the limits of experimental error. Chloroform also caused a shift in the position of the maximum to approximately 333 mμ; the other solvents caused no shift detectable with certainty, except that with cyclohexane the maximum appeared to be nearer 330 mμ than 328 mμ. Morton[1] found that chloroform gave low results, but attributed the phenomenon to instability of vitamin A in this solvent. Although vitamin A certainly is unstable in chloroform, this is not sufficient to explain our findings. A chloroform solution of halibut-liver oil gave a value $E^{1\%}_{1\text{cm}}$ 328 mμ $= 26{\cdot}4$; the chloroform was evaporated from this solution under reduced pressure and replaced by an equal volume of ether: this ether solution gave $E^{1\%}_{1\text{cm.}}$ 328 mμ $= 31{\cdot}7$; a direct solution in ether gave $E^{1\%}_{1\text{cm.}}$ 328 mμ $= 31{\cdot}8$.

The materials listed in the table fall into two groups, comprising on one hand the first two oils, and on the other the third oil and the two concentrates. Relative in each instance to the absorption in alcohol, the first group shows greater enhancement of the absorption in ether and less depression in chloroform than does the second group. These irregularities are probably due to differences in the proportion of *cis-trans* isomers of vitamin A. These isomers may not only have different absorption coefficients in any one solvent, but also the ratio of these coefficients may vary from solvent to solvent. Possible differences between the biological activities of the isomers may help to explain the various factors reported relating $E^{1\%}_{1\text{cm.}}$ 328 mμ to biological units.

We have further observed that irradiation of solutions of vitamin A sometimes increased and sometimes decreased (by so much as 40 per cent) the absorption at 328 mμ, but that the absorption almost returned to the original value after the irradiated solution had stood in the dark. Variations in the proportion of *cis-trans* isomers might explain these results and also some of the spontaneous increases as well as decreases in absorption of liver oils and concentrates during periods of storage which have been observed by ourselves and others (*cf.* Heilbron, Gillam and Morton[2]; *cf.* also the experiences of Holmes and Corbet[3] with crystalline vitamin A and of Zechmeister and Tuzson[4] with lycopene).

It is intended to publish full details elsewhere of the work summarized here and additional work now in hand.

Note added to proof. Since submitting this letter for publication we have learned that Dr. A. E. Gillam and Dr. M. S. El Ridi have—independently of ourselves—studied the effect of solvents on the vitamin A absorption spectrum.

[3] Holmes and Corbet, *J. Amer. Chem. Soc.*, 59, 2042 (1937).

[4] Zechmeister and Tuzson, NATURE, 141, 249 (1938).

THE above authors have been good enough to show me their letter. The 1934 Conference was concerned with a substitute for the bio-assay with its experimental error of perhaps ± 25 per cent for individual assays. The fact that variations of a few per cent for spectrophometric assays in different solvents like alcohol and cyclohexane are now being noted is an indication of the progress made. Such variations are usual for polar molecules and do not invalidate the spectrophotometric method.

The possibility of variable proportions of geometrical isomerides in different vitamin A containing materials has been obvious since the polyene formula was established. So many isomerides are theoretically possible with five ethenoid linkages (four in a straight chain) that the problem of their occurrence has long defied experimental attack, and it has been reasonable to assume a balancing of effects.

With one double bond as in *cis* and *trans* stilbene and cinnamic acid[1], differences in ε max. are of the order 2 : 1, an effect much larger than that observed except in the valuable irradiation experiment.

I have approached the problem from another angle. Hitherto the ultra-violet absorption (328 mμ) and the $SbCl_3$ colour test maximum (620 mμ) have shown a nearly constant ratio $E^{1\%}_{1\text{cm.}}$ 328 mμ/620 mμ of 0·32 for rich preparations. A halibut intestinal oil prepared by Dr. Lovern has been subjected to molecular distillation by the courtesy of Dr. F. H. Carr of Messrs. British Drug Houses, Ltd. In the different fractions the ratio varies from 0·21 to 0·38 and for a range of very rich ester fractions it is *c.* 0·28. A partial separation of *cis-trans* isomerides is a plausible explanation.

Specificity of Disaccharide-splitting Enzymes

DISAGREEMENT exists concerning the substrates which maltases of different sources can hydrolyze. According to the view advanced by Leibowitz[1], there occur in Nature two types of maltase, a gluco-maltase and a glucosido-maltase respectively. The gluco-maltase which occurs in malt and in moulds splits maltose but is inert towards alpha-glucosides and sucrose: the glucosido-maltase which occurs in yeast splits alpha-glucosides as well as maltose. Different investigators[2] have applied the two maltase classification over a wide range of maltases from various sources. Weidenhagen[3], however, has denied the validity of this view, and claims that in sufficient enzyme concentrations, even malt and taka-diastase hydrolyze alpha-methyl-glucoside. All maltases in Nature are said therefore to be glucosido-maltases; they are considered to be identical with the gluco-sucrase among the sucrases, and to split alpha-glucosides and sucrose as well as maltose.

In the course of a series of tests on the heat stability of different lots of taka-diastase, taka-maltase preparations were found which were peculiarly resistant to inactivation by heat. This property has enabled us to make additional observations on the question of the specificity of taka-maltase. If a solution of the enzyme is heated to boiling point, these resistant preparations lose their ability to split sucrose and also what slight activity they formerly possessed to split alpha-methyl-glucoside; they retain, however, or regenerate after the heating, most of their ability to split maltose.

It follows, therefore, that the inversion of sucrose by taka-diastase is not even partially due to taka-maltase but to a distinct taka-sucrase. It seems reasonable also to believe with Pringsheim that the slight alpha-glucosidase action observed by Weidenhagen in concentrated taka-diastase preparations was due to the admixture with the predominant gluco-maltase in mould of a small quantity of glucosido-maltase.

A further proof that yeast maltase and taka-maltase are different was furnished by a study of the effect of taka-diastase on yeast maltase solution. Yeast maltase solution incubated for a definite time interval with a sufficient concentration of taka-diastase loses completely its ability to hydrolyze either alpha-methyl-glucoside or maltose. The ability of the taka-maltase to split maltose is not, however, removed under these conditions. Taka-diastase thus contains an inhibitor for yeast glucosido-maltase. The inhibitor is heat labile, non-dialyzable and distinct from taka-maltase.

The nature of the 'heat-stable' taka-maltase, the manner of inhibition of the yeast maltase, and in particular the effect of the inhibitor in taka-diastase upon maltose fermentation by zymase will be reported in detail elsewhere.

Action of Molybdenum in Nutrition of Milking Cattle

A LARGE area under pasture in Somerset cannot be grazed by cows during the normal grazing season (April–October) without milk yields falling rapidly, causing marked loss of condition and even death. The disorder, which has been known for very many years, is marked by extreme diarrhœa; other cattle and sheep also scour on such herbage, though the loss of condition is not so obvious as with the milking animal. Such fields are described as being 'teart'. The area involved is estimated at about 20,000 acres by Gimingham[1], and the annual loss to the farming community must be very great. The available information seems to rule out bacteria, parasites, water supply or a particular herb as causal agents, and points to the presence of some constituent of the soil taken up by the herbage[2].

Spectrographic examination of a few samples kindly supplied to us by Mr. A. W. Ling and Mr. W. R. Muir of the University of Bristol showed the presence of molybdenum in 'teart' herbage. A more extensive and systematic examination which we have since conducted on 'teart' and 'non-teart' fields in Somerset has confirmed the fact that the molybdenum content of 'teart' herbage is considerably higher than that of the 'non-teart' fields situated close by.

There is no apparent correlation between the total or HCl-soluble molybdenum of the soil and that of the herbage. Comparisons are, however, complicated by the fact that 'teart' and 'non-teart' fields are managed in such a way that the herbage is at different stages of growth at any one time of the year.

We have fed soluble molybdates in quantities equivalent to those provided in an average daily ration of really 'teart' herbage (1·36 gm. Mo per head per day) to five dry cows at Jealott's Hill, and in three cases have produced extreme scouring and loss of condition similar to that which occurs in 'teart' fields in Somerset. Whether the molybdenum is directly responsible or whether it catalyses a toxic product in the rumen we do not yet know. It is generally stated in the 'teart' areas that horses are not affected, but it is impossible to say at present if this is due to the simple stomach or to differences in grazing habit.

The investigation is still being pursued. Our thanks are due to Mr. Milbourn of I.C.I. (Metals), Ltd., for the spectrographic examination of the early samples from Bristol.

Potential Changes in the Ears of Reptiles and Fish

Wever and Bray's work has shown that in mammals the cochlea behaves like a microphone, giving electric oscillations which are an accurate transcription of the sound waves. The most plausible explanation of the effect is that of Hallpike and Rawdon Smith, namely, that it is due to the vibration of a polarized membrane separating endolymph and perilymph, but other hypotheses have been put forward.

The object of this communication is to direct attention to the similar effect in the inner ears of cold-blooded vertebrates. In alligators there is a cochlea, and it is not surprising to find potential changes, as in mammals, copying the sound waves. In lizards the potentials which can be detected in the inner ear are of the same form, but are much smaller. In tortoises they are often too small to be distinguishable from artefacts due to electrode movement. In the eel, however, the inner ear structures are more accessible and large potential oscillations can be recorded from the saccule when the head is exposed to vibration. The saccular response in the pike, described by Piper (1910)[1], is presumably due to the same cause. The frequency of the potential changes which can be induced in the inner ear seems to be limited merely by the frequency at which the structures can be made to vibrate; the maximum frequency of response in the fibres of the auditory nerve is much lower, since there must be time for recovery after each impulse.

Activity and Insect Survival

WHILE laboratory experiments have revealed new facts of insect biology, some have given results which have been interpreted in such a way as to cause confusion. Experiments measuring longevity have often given ambiguous results. At present, much work is being done on the survival of the bed-bug, *Cimex lectularius*, and as this insect is a domestic pest usually found in confined spaces, it appears at first sight admirable for laboratory study. Imprisonment among paper in a tube differs little from the conditions of the normal environment. Yet the times of survival found by various investigators[1,2,3] working under similar climatic conditions are so different that it is, for example, quite impossible to say how long bugs must be left in an unoccupied house with no sources of food before they will all die from starvation.

Recent experiments throw some light on the subject. When newly emerged, unfed and unfertilized females of *Cimex lectularius* were starved, singly, in 3 in. × ½ in. glass tubes at 30° C. (86° F.) and 25 per cent relative humidity, in darkness except when examined, they survived on an average 134 days (limits 116 and 145 days, standard deviation 9·1). The insects seldom moved more than a few millimetres. Now if similar bugs after only one week's starvation were put on an open and well-illuminated surface, they would run about rapidly. If they were kept running for several minutes, and then allowed to feed, they survived; but if they were *not* fed, they died in a few hours. The extra activity due to running for several minutes was apparently sufficient to exhaust reserves which would have kept a resting bug alive for several months. In the longevity experiments mentioned above, I took particular care not to disturb the insects when examining them, and thus obtained a length of life far longer than that previously found by other workers under similar climatic conditions.

It is not unlikely that by using suitable methods we shall find that at temperatures comparable with those occurring naturally in Great Britain, bugs will be able to survive for years. The variability of previous workers' results appears to depend on the extent to which their technique disturbed the insects; in the field, conditions which affect activity will affect longevity, not only with *Cimex* but also with other species. Experiments must be planned to make allowances for this important factor. In the case of the bed-bug we must discover what internal and external stimuli cause activity and hunting for food, and how often unsuccessful individuals die from exhaustion.

Occurrence of young *Ophiothrix fragilis* within the Genital Bursa of the Adult

IT has been recorded by Mortensen[1,2,3] that young specimens of the ophiuroids *Ophiothrix fragilis* Abildgaard, *O. triglochis* M. and Tr. and *Ophiactis Kröyeri* Ltk. are sometimes to be found clinging to the arm spines of the adults. The occurrence of the young individuals on the adults does not, in Mortensen's opinion, indicate a viviparous habit in these ophiuroids since one, at least, namely *O. fragilis*, is known to have pelagic larvæ; rather, it is "quite by chance that the young ones, after their metamorphosis from the pelagic larvæ, happen to settle down on adult specimens in places where these latter occur in good numbers"[2].

In view of this 'accidental' appearance of the young ophiuroids on the arm spines of the adult, it would be unwise to assume that their presence, even within the adult genital bursa, was, in itself, an indication of a viviparous habit. Fedotov[4], who found a specimen of *Gorgonocephalus eucnemi* M. and Tr. with a young individual in the depth of the bursa was inclined to regard *Gorgonocephalus* as viviparous, although he considered the question, on such evidence, as not being entirely solved.

While working at the Plymouth Marine Biological Laboratory in December last, I examined some two hundred specimens of *O. fragilis* and found that about 10 per cent of that number had young *Ophiothrix*, of a disk diameter of 0·25–0·5 mm., clinging to the spines and tube feet of the oral side of the arms. The number present on a single individual varied from one to fifteen. In five of these individuals, however, much larger specimens (of about 2 mm. disk diameter) were found *within the bursa*, one in each adult. The presence of young brittle-stars within the bursa of an oviparous species demonstrates conclusively that their presence does not necessarily indicate viviparity.

In the case of *O. fragilis*, the young post-metamorphic stages find shelter among the spines of the older individuals, from which they can only be dislodged with difficulty owing to their habit of wrapping round the spines and attaching themselves by means of their arm hooks. With increasing size, attachment becomes a matter of greater difficulty and it may be supposed that the larger specimens, in search of better shelter, occasionally move towards the openings of one of the bursæ and crawl inside, there to settle until they become too large to be housed in comfort. They would then leave the bursa and seek the shelter of a rocky crevice or stone as is the habit of the species.

On this assumption, the bursa would be regarded as a convenient habitation, rather than a nursery, for the post-metamorphic brittle-stars.

Effects of Soft X-Rays upon Chætopods

THE effects of X-rays upon *Tubifex tubifex* and some other members of the class Chætopoda have been investigated by Stone, Turner, Zhinkin and others. They have reported, in general, that hard X-rays inhibited or destroyed the capability of regeneration, because it destroyed the neoblasts, although in appearance the general body tissue was little affected by their dosages.

It occurred to us to investigate the behaviour of *Tubifex tubifex* when irradiated with soft X-rays from a copper target X-ray tube operated at 30 kv. and 10 ma. The most intense part of the radiation had a wave-length of 1·54 A., which, being less penetrating, might be expected to produce more drastic effects. The radiation was collimated by a narrow slit and allowed to strike selected somites of the animals placed 1 inch from the focal spot of the X-ray tube.

It was expected that the irradiated somites would be injured or killed, so that the animals would break into two parts, each of which would live just as though the animals had been cut into two parts with a scalpel. Actually it was found that irradiation of the first three to five somites resulted in the formation of protuberances of various sizes. These were either reabsorbed or the anterior section disintegrated. When the heart region was irradiated, no injuries were observed in a majority of the animals. Irradiation of the somites approximately in the middle of the animal caused it to break at the site of irradiation into two parts, but in more than 70 per cent of the cases the posterior section died, whereas had the animal been cut into two, both sections would have survived in almost every case.

The time of irradiation was 3 minutes in each set of irradiations. Histological studies are to be made of the injured sections, and further irradiation experiments are planned. We expect to publish a fuller treatment of the data at an early date.

Band Spectrum of Indium Hydride

IN connexion with investigations now in progress on some hydrides in the third group in the periodic system, I have studied the spectrum of indium hydride. The bands were obtained in the emission from an arc burning between electrodes of indium and carbon in hydrogen at high pressure, using the same conditions as in a previous investigation of the thallium hydride[1].

The spectrum of InH was photographed between 2200–8500 A. (dispersion 1·9 A./mm.). In the range between 5600–8500 A. several bands were observed, which probably belong to InH. Three of these bands with $\nu_0 = 16{,}904{\cdot}9$, $17{,}574{\cdot}1$ and $16{,}148{\cdot}2$ cm.$^{-1}$ were analysed.

The band, $\nu_0 = 16{,}904{\cdot}9$, consists of single P-, Q- and R-branches, corresponding to a ${}^1\Pi \rightarrow {}^1\Sigma$ transition. This band is degraded toward the violet, but at high J-values all three branches form 'secondary' heads. In the Q-branch all lines up to $J = 31$ are intense. $Q(32)$, however, does not appear, even if the pressure in the arc is increased to ten atmospheres, which indicates a pronounced predissociation. In the secondary head of the P-branch, above $P(20)$, the lines are too crowded to be distinguished, but the R-branch can be followed steadily up to $R(33)$. The intensity distribution in the R-branch is perfectly normal, and no sudden interruption of the branch can be observed. All this indicates a case of predissociation similar to that earlier known in the spectrum of MgH.

The two other bands with $\nu_0 = 17{,}574{\cdot}1$ and $16{,}148{\cdot}2$ consist of single P- and R-branches, degraded to the red, and correspond to a ${}^1\Sigma^* \rightarrow {}^1\Sigma$ system with (0,0) and (0,1) transitions, the lower state of (0,0) being identical with that of ${}^1\Pi \rightarrow {}^1\Sigma$. The following rotational constants have been calculated :

$$\begin{aligned} {}^1\Sigma\ , \quad B_0 &= 4{\cdot}921, \quad D_0 = 2{\cdot}24 \times 10^{-4}. \\ {}^1\Pi\ , \quad B_0 &= 5{\cdot}266, \quad D_0 = 3{\cdot}28 \times 10^{-4}. \\ {}^1\Sigma^*, \quad B_0 &= 4{\cdot}883, \quad D_0 = 3{\cdot}77 \times 10^{-4}. \end{aligned}$$

Besides these some bands appear in the red and infrared. The more intense heads can be classified in the following two groups :

Band heads, degraded to the	
violet	red
16,906 cm.$^{-1}$	17,724 cm.$^{-1}$
16,828	16,788
16,163	16,467
	16,366
	15,981
	15,506
	14,227

The search for the still unknown spectrum of gallium hydride is now in progress.

Further details concerning the band spectrum of indium hydride will be published later.

Science and the Unobservable

IN his Royal Institution discourse, published in a Supplement to NATURE of January 1, Prof. H. Dingle has made an attempt to show that, if we regard the recent trend of physics (expressed by the principle : "nothing which is logically or physically unobservable is significant") as legitimate, we are idealists. This is no new conclusion and the very thing to which M. Maritain[1] and R. J. Dingle[2] object.

It seems that Prof. Dingle does not realize exactly for what reasons we can disagree with Einstein when he says that : "The concept [of simultaneity] does not exist for the physicist until he has the possibility of discovering whether or not it is fulfilled in an actual case. . . . As long as this requirement is not satisfied, I allow myself to be deceived as a physicist (and of course the same applies if I am not a physicist), when I imagine that I am able to attach a meaning to the statement of simultaneity".

When we speak as physicists, we consider only phenomena which are observable with physical means. When we speak as non-physicists, we consider, besides physical observation, also other means of apprehension. We can only pretend that the two ways of speaking are the same, if it is proved that we have no other means of apprehension than physical ones, that is, sense-perception. But if we do have such superior faculties, we cannot conclude that our limitations when we are using only a part of our faculties (physical means) are the same as when we are using all our faculties.

In the particular case considered here, the question therefore comes down to this : Can we, by means of our present human faculties, reach the idea of simultaneity without observing it physically ?

In order to make it easier to answer this question, let us apply the above-mentioned principle (rejection of physically unobservables) to Prof. Dingle's article. What will be the result ? By means of pure sense-perception, we see black signs on white paper; we can measure these signs and investigate the physical properties of the materials. But if Prof. Dingle says that there is more than that in his paper, we will be obliged to reject this opinion because the reasoning which he wants us to understand is physically unobservable. This is our attitude as a pure physicist. But man has an intellect; he not only *knows*, he can also *understand*. He can have abstract ideas: 'the unobservable', 'truth', 'simultaneity', etc. In practice we cannot talk as 'pure' physicists. As human beings we always use our reason in addition to our sense-perception and we always reach to some extent the physically unobservable. It is for this reason that Prof. Dingle's article means more to us than paper and ink.

It seems clear that universal ideas, first notions on which all our reasoning is based and on which mathematics and science in general rest (axioms, postulates), are beyond sense-perception and physical observation. Our mind enables us to escape from the relative and reach the absolute.

Prof. Dingle's words: "M. Maritain and those who agree with him claim that the simultaneity of spatially separated events is something independent of our means of observing it. When asked what it is, they claim that its nature is immediately evident and that everyone knows it. But Einstein says he does not know it, and Einstein is an honourable man. And the only reply is that Einstein and his followers must be speaking as physicists" do not correctly state the question. Simultaneity is independent of *physical* observation, but not necessarily of the 'observation' of our minds. The abstract idea of simultaneity is immediately evident in the sense that we have (or should have) this evidence because we are rational beings. If Einstein believes that he has not this evidence, it may be because he did not consider sufficiently the question from this angle, or because he did not fully appreciate the power of mind[3].

In order to check idle invention, but to keep in mind our intellectual faculties, we need only replace the word "physically" by "essentially" in the above principle. Nothing which is logically or essentially unobservable is significant.

Prof. Dingle seems to be perfectly right when concluding that divergence of opinion results from a difference of philosophical attitude. One may say that physicists are not always sufficiently aware that they are sometimes talking as metaphysicists. As a physicist, Einstein may base a theory on the assumption that 300,000 km./sec. = infinity, but as a rational man he has no right to maintain this postulate, because our mind is not limited by the speed of light, a physical phenomenon.

S. VAN MIERLO.

9 Rue Pierre Bertin,
Versailles.
Jan. 14.

---

[1] "Reflexions sur l'Intelligence", pp 202–261

[2] "The Faith and Modern Science", pp 40–56.

[3] Other men of science, like Prof Max Planck, who have paid a good deal of attention to the philosophical side of such questions, are fully aware of having such evidence. See "Positivismus und Reale Aussenwelt" (Leipzig 1931) and "Religion und Naturwissenschaft" (Leipzig, 1937)

PROF. DINGLE arrives at a startling conclusion, namely, that if any physicist believes that "the universe exists independently of our experience of it" he must also "presume that he is omniscient" (p. 28). This conclusion is reached in the course of an examination of the current principle in physics that only observable quantities are significant. In his reasoning, however, I think that he makes the mistake of overlooking the admittedly limited and in large part tentative character of all scientific knowledge.

To avoid misunderstandings of this sort, I think that Prof. Dingle's statement of the principle of observability needs to be amplified a little, perhaps as follows: Only that which is practicably observable —that is, only that which would be observable if we were able to use known means of observation to the known limits of their possibilities—can form part of present scientific knowledge, and only that which may hereafter become physically observable in this sense is to be admitted into the science of the future. In this form the principle does not deny the existence of what is unobservable, but merely locates it outside the realm of scientific knowledge; and it does not imply the claim that the physicist can make, here and now, a *final* classification of ideas into observable and unobservable, which would indeed partake of omniscience. More sweeping statements can be found, to be sure, among the commentators on modern physical theories, whose eloquence seems sometimes to outstrip their scientific caution, but scarcely in the professional writings of the *creators* of the new theories.

To take the example cited by Prof. Dingle, it is a fact that absolute simultaneity is unobservable in terms of modern physics, since known laws furnish us with no means of detecting it. To many minds there seems to exist a strong presumption that it will always elude detection, but this presumption can never rise to a certainty; Einstein himself would admit the possibility that a signal travelling with infinite speed may some day be discovered, and that in a certain sense absolute simultaneity would then become an observable thing. When Einstein said, in the passage quoted by Prof. Dingle, that the term had "no meaning", he was referring, I think, to a meaning in terms of present-day experience, and he ought to have said so. It can scarcely be doubted that he would allow to the concept of absolute simultaneity a meaning in the same sense as there is a meaning to the depth of the rabbit-hole down which Alice fell; in this sense we can all follow M. Maritain in distinguishing the meaning of a concept from its use.

Most physicists undoubtedly believe in the existence of a real world different from their own experiences; they feel that this concept best fits the fact that the performances of physical apparatus are largely independent of their own volition. (If I did not believe this, I should have difficulty in believing in the existence of Prof. Dingle.) But they do not claim the ability to explore this external world *completely*; and they will not bother to consider whether things that are destined to remain permanently beyond observation exist or not. "Trivial" our knowledge of the world may be, as viewed from the point of view of some non-human being; but this possibility, apparently disturbing to Prof. Dingle, is surely not a professional cause of annoyance to the working physicist, and I do not think it should seriously disturb any of us. Human experience is the ultimate source of all scientific knowledge, and what lies entirely outside of human experience, and is therefore unobservable, is no concern of science.

Recognition of the limited scope of its generalizations and indifference to the unattainable seem to be two of the most valuable traits of the modern scientific method as contrasted with the speculations of the medieval philosophers, and I think that these are features which might well be introduced in much larger measure into other realms of human thought.

E. H. Kennard.

Cornell University,
Feb. 17.

Mr. Van Mierlo makes two assumptions, neither of which accords with fact—namely, (1) that physics is distinguished from other studies by the instruments employed; and (2) that reason is not an instrument employed by the physicist properly so-called. With regard to the second, I would point out that most of the things to which the physicist attaches significance (for example, the interiors of the earth and stars, the occurrence of unobserved eclipses, etc.) are not observed by the senses, but apprehended by reason. On the first point it is surely common knowledge that the distinguishing characteristic of physics (and that purely for convenience) is not its instruments but its subject-matter. The physiologist who uses a galvanometer does not thereupon become a physicist, and if a physicist used a stethoscope, or even logic, to attack a physical problem, his work would not on that account be refused publication by the Physical Society. The determination of the time of occurrence of a physical event is a physical problem, and if the times of occurrence of two events are identical, the events are simultaneous. If Mr. Van Mierlo could determine those times for two spatially separated events *by any means at all*, and get results which are independent of his velocity (such velocity being defined, of course, in terms consistent with the definitions of the times and distances of the events, or the process would be irrational), physicists would acknowledge the obligation to revise their theories accordingly.

Prof. Kennard wants to remain a realist, that is, to believe in a world existing independently of experience; to avoid the stigma of a profession of omniscience; and to approve the scientific rejection of absolute simultaneity. Notwithstanding his letter, I do not see how this is possible.

Let A be the world in question, and A' that part of it which we can now experience. Then, as a realist, Prof. Kennard must admit that there may be a part, $A\text{-}A'$, which is not experienced. As a non-professor of omniscience he must further admit that when he has discovered A'', the portion of $A\text{-}A'$ which the complete exercise of known means of observation would allow him to discover, there may still remain a portion, $A\text{-}A'\text{-}A''$, which is beyond his knowledge. Now, absolute simultaneity does not belong to A' or A''. Hence, either it belongs to $A\text{-}A'\text{-}A''$ or it does not exist. As a realist, Prof. Kennard must admit a significant distinction between these alternatives; and, as a non-professor of omniscience, he cannot decide between them. He can therefore make no pronouncement on the matter. But the principle of relativity says: "It is impossible to detect motion relative to the ether"; and this is equivalent to a denial of existence to absolute simultaneity. It therefore *does* make a pronouncement on the matter. Prof. Kennard must therefore reject it; or cease to be a realist; or profess omniscience.

It is not a mere matter of words. Relativity does not merely say that we cannot now detect absolute simultaneity; we knew that before the theory was put forward. That is simply a statement of the *problem* aroused by the Michelson-Morley and other experiments, but relativity professes to be a *solution* of that problem. It proceeds to organize the experience we have in a way which would be invalid if absolute simultaneity were unobservable merely from temporary lack of knowledge.

I think that Prof. Kennard's reluctance to accept this conclusion arises from a mistaken notion of what idealism (in the sense implied in this discussion) means. He introduces the question of volition, but that has nothing to do with the matter. Certainly our observations are largely independent of our volition, but the question is simply whether we are to assign significance to "existence" independently of observation, voluntary or otherwise. When Prof. Kennard made the experiment of looking at Nature of January 1, he saw marks which his rational mind interpreted in terms of a hypothesis called Dingle. The performance of his eyes did not depend on his volition—the marks which he saw had nothing to do with what he would have liked to see—and he could not make rational sense of his experience without the hypothesis referred to, however much he might have preferred to ascribe it to an illusion produced directly by the devil. All that holds good whether he is an idealist or a realist. The question is simply whether scientific progress is best described by saying that we start with experience and grant existence only to that which is necessary to correlate such experience rationally, or that we start with a hypothetical world independent of experience and proceed to find out all that we can about it.

Herbert Dingle.

Imperial College of Science,
London, S.W.7.

The Advancement of Science and Society

We are glad to read the letter in Nature of March 19, under the above heading, from Dr. F. R. Moulton, Permanent Secretary of the American Association for the Advancement of Science. It need scarcely be said that the invitation from that body to the British Association to co-operate in forming the nucleus of a wider organization for this great object is engaging our earnest attention, and has already been brought to the notice of the Council of the British Association. We look forward to meeting Dr. Moulton and some of his colleagues this summer, to discussing the project with them, and to having them with us at our meeting in Cambridge. It may be added in regard to the last clause in Dr. Moulton's letter concerning the "planning of the necessary machinery", that a scheme in rough outline has already been forwarded to him for informal comment, in the hope that it may prove possible, whether on the basis of that scheme or of some other, to lay practical proposals before the governing bodies of both Associations at an early date.

P. G. H. Boswell.

March 21.

Dementia Nomenclatorica Americana

UNDER the above heading, I wrote to NATURE of November 16, 1935, expressing consternation at the ever-increasing hypertrophy in the nomenclature of the Foraminifera. I have continued to correspond with my friend Dr. H. E. Thalmann, and it may interest readers of NATURE to note that, in the last six years, more than two thousand papers have been published upon these Protozoa. These papers give us sixty new families and sub-families, two hundred new genera and sub-genera, and two thousand four hundred new species and varieties. This gives us two to three new genera per month, and two new species per day.

The brain reels and the senses gape at what might be an even partially complete synonymy to-day, and with what the systematists will be confronted in, say, *another* six years is not pleasant to contemplate.

Editors (and others) might do worse than establish a rule to the effect that henceforward no synonyms shall be allowed other than those immediately following d'Orbigny, and up to and including H. B. Brady and his contemporaries.

And—to adopt the terminal terminology of Acts of Parliament: "The Conchyliologie Systématique of Denys de Montfort is hereby repealed."

Since the above was written I have received from Java a paper upon "a second species of *Biplanispira*, etc." This starts a new group of specific names. May we hope before long to add to our nomenclature, *Monoplanulina*, *Hydroplanispira*, *Junkeria*, *Fokkerinoides*, *Handley-Paginella*, and *de Havillandia*? At any rate this would immortalize men who have left the impress of their names upon science, and convey more to posterity than the too-familiar collaborators, who for lack of early literature give us, in turn, *Smithia jonesii* and *Jonesia smithii* for slightly differing forms of *Truncatulina variabilis*—which is no longer *Truncatulina*, but has turned *Cibicides* in a single night.

EDWARD HERON-ALLEN.

British Museum (Natural History),
S.W.7.

'Convergent' Sunbeams

FROM observations made on three different occasions during past few summers, I can corroborate in every detail 'convergent' sunbeams reported by J. J. Hopfield[1]. Always in the late afternoon, the sun just having set behind the Jura and sending out 'fan-like' beams of alternating light and shade, there seemed to be issuing from the opposite horizon behind the Savoyard Mountains (Mont Blanc) similarly radiating beams. Though somewhat faint overhead, the continuous course of these bundles could be clearly traced between the eastern and western horizon.

Only recently a friend told me that flying over Mexican waters about a 1,000 ft. up during the solar eclipse he found himself to be the centre of converging beams from the corona.

ARNOLD C. KLEBS.

Les Terrasses,
Nyon (Lake Geneva).

[1] NATURE, 141, 333 (1938).

THE striking phenomenon reported by Dr. J. J. Hopfield[1] is occasionally seen in Great Britain. I have witnessed two excellent examples, one on June 24, 1935[2], and another on September 12, 1936[3], at Hastings. Mr. W. L. Baxter has recorded a similar occurrence on March 17, 1934, at South Farnborough, Hants[4]. In two of the cases mentioned, the sun had set 20–25 minutes previously. The rays were pale rose or delicate pink in two of these records and orange-yellow in the remaining one, and were of considerable width. The rays extended completely across the sky from north-west to south-east on June 24, 1935, and from west to east on September 12, 1936, and convergence due to perspective was extremely well and strikingly seen. These rays are perhaps more likely to be observed in thundery weather when hard and well-defined cumulus clouds may be ranged low down on the horizon (or even below the horizon) so that protuberances on the cloud throw shadows much in the same way as is commonly seen when the sun is shining brightly behind well-defined cumuli during the daytime. In the latter case rays may be both projected upwards and radiating from the sun as a centre if the cloud is large and unbroken and with a hard summit, or projected downwards to the ground (a much commoner occurrence) if there are breaks or holes in the cloud sheets.

In connexion with the latter example it was an old idea that these rays meant coming rain, and an old saying, "The sun is getting up his back stays, and it is time to look out for bad weather" refers to this; also these rays gave rise to a saying that the "Sun is drawing water" and rain will soon follow.

A. E. MOON.

39 Clive Avenue,
Clive Vale,
Hastings.

[1] NATURE, 141, 333 (1938).
[2] Met. Mag., 70, 158 (1935).
[3] Met. Mag., 71, 210 (1936).
[4] Met. Mag., 69, 119 (1934).

THE necessary conditions for the phenomenon of convergent sunbeams are a slight haze spread evenly overhead, and a few small cumulus clouds on the eastern horizon. The best example that I have seen was at sea while travelling from Cape Town to Durban at Easter 1899. By good fortune, Mr. R. T. A. Innes, then secretary of the Cape Observatory, and others were on board, and there was opportunity for careful observation and comparison of notes.

There was a beautiful sunset; cloud shadows radiated from the sun, converging toward a point as far below the horizon as the sun was above it. As the sun set this point rose and the rays met at the eastern horizon. Long bands of pink and blue arched over our heads and over most of the sky like markings of a huge melon. One could have sworn that they were curved—obviously curved—but they were really straight and parallel. A drawing or photograph of any small portion of the sky would have shown straight lines. To the north, south or overhead they would have been parallel, to the east or west they would have been straight but converging. After the sun had set, the converging point rose and a solid-looking blue band touching it, rose too. This was the shadow of the earth, which may often be seen in the east after sunset.

If there is a cloud partly within the band, and partly illuminated by the sun, its height may be calculated. I remember discussing this with Mr. Innes and I tried to perform the calculation, but I saw that refraction would have a considerable effect, and I did not see how to make a quantitative allowance for it. By a curious coincidence, I have just received a copy of a paper by Prof. H. Dember, of the University of Istanbul, which includes a diagram almost identical with one which I sketched in my pocket-book a couple of days ago after discussing the matter with a scientific friend, who agreed that allowance must be made for refraction.

A. P. Trotter.

Greystones,
Teffont, Salisbury.

A phenomenon similar to that described by Dr. John J. Hopfield was well seen by a colleague (Mr. H. F. Finch, then of Abinger Magnetic Observatory) and myself from the summit of Leith Hill, Surrey, in September 1926. My recollection is that the clouds casting the apparently converging shadows were a little to the east of the zenith, and the beams were no doubt brought into prominence by a slight dust haze.

The rarity of the phenomenon must be attributed to the rather precise nature of the conditions necessary; namely, a clear western sky with the sun on the point of setting and a broken line of low cloud lying approximately at right angles to the direction of the sun. The beams passing through the interstices, being practically horizontal, will then appear to converge on the eastern horizon by perspective.

W. M. Witchell.

Royal Observatory,
London, S.E.10.

Points from Foregoing Letters

By means of an improved canal ray tube of Dempster type which gives sharp displaced lines, and with a diffraction grating of 15,000 lines to the inch, Dr. H. E. Ives has observed a displacement of hydrogen lines of approximately 0·05 A. towards the red, *independent of the orientation of the apparatus*. This positive effect confirms the Larmor and Lorentz theory of the relation between matter and the luminiferous ether, according to which a moving clock (in this case the hydrogen molecules emitting the light waves) has its rate decreased in the ratio $\nu = \nu_0 \sqrt{1 - V^2/c^2}$.

A table showing the effect of various solvents (alcohol, cyclo-hexane, hexane, ether, chloroform) on the intensity of absorption in the region 328 mμ by substances containing vitamin A (halibut and fish oils and concentrates) is given by E. L. Smith, B. E. Stern and F. E. Young. The variation is about 20 per cent in the various solvents; chloroform shows a shift in the maximum absorption to approximately 330 mμ. The effect of the solvents is not the same on all the oils investigated and this, as well as the effect of irradiation and storage upon the oils, is tentatively ascribed to the presence of *cis-trans* isomers of vitamin A.

Dr. R. A. Morton, commenting on the above, states that after molecular distillation of halibut intestinal oils, different fractions show a variation in the ratio of the ultra-violet absorption to the antimony chloride colour test maximum, and this also could be plausibly explained by a partial separation of the *cis-trans* forms.

According to Dr. J. Leibowitz and S. Hestrin, certain taka-diastase preparations lose their hydrolytic activity towards sucrose and their slight hydrolytic activity towards alpha-methyl-glucosides, but retain or regenerate most of their hydrolytic ability towards maltose when heated in boiling water. By incubation with taka-diastase, a complete inhibition of yeast maltase may be obtained. Hence yeast-maltase and taka-maltase, the authors conclude, are essentially different in character.

The deleterious effects which herbage grown on the so-called 'teart' areas of Somerset has on milking cattle is due, according to experiments by W. S. Ferguson, Dr. A. H. Lewis and Dr. S. J. Watson, to the presence of excess of molybdenum in the soil and in the herbage therefrom.

Prof. E. D. Adrian reports that, as in the case of the mammals, the cochlea in the ears of reptiles and fishes behaves like a microphone; sound waves give rise in them to electrical potential changes.

Activity in bed-bugs increases the metabolic rate and causes death in a fraction of the time in which resting bugs die. Dr. Kenneth Mellanby directs attention to the importance of considering activity as one of the principal factors in laboratory experiments made to study insect biology.

The occurrence of the young of the brittle star, *Ophiothrix fragilis*, in the genital bursa of the adult is, according to Dr. J. E. Smith, an accidental occurrence, and the bursa may be regarded as a convenient habitation rather than a nursery for the post-metamorphic stage.

According to H. Kersten and H. Branson, irradiation of the first three to five somites of a chætopod usually resulted in the formation of protuberances of various sizes. The heart region was much more resistant; the majority of the animals showed no ill-effects. Irradiation of the somites approximately in the middle of the animals generally resulted in a cleavage at the point, with the death within 24 hours of the posterior section.

Details of the band spectrum of indium hydride, observed in the region 5600–8500 A., are given by Dr. B. Grundstrom. The spectrum was obtained from an arc between electrodes of indium and carbon in hydrogen at high pressure.

Commenting on Prof. Dingle's dilemma that modern physics with its assumption that *only that which is logically or physically observable is significant*, leads one either to assume omniscience, or to deny the existence of the external universe, S. Van Mierlo points out that, by using reason in addition to sense perception, one always reaches the physically unobservable. He suggests that, in the statement of the principle, the word *physically* should be replaced by *essentially*. Prof. E. H. Kennard would avoid the dilemma by admitting that the limits of the observable are being continuously extended and that, for example, if a signal travelling with infinite speed were one day discovered, simultaneity would become observable (to observers moving relatively to one another). Prof. Dingle, in reply, considers that neither of these views solves the problem.

Research Items

Natives of Bentinck Island, Queensland

An account of two islands, little known outside Australia, which lie off the coast of Queensland, is given by Mr. Ewen K. Patterson in *Discovery* of March. Of these St. Helena, about five miles from the east coast, was formerly a convict station and is now being converted into a pleasure resort. The second, Bentinck Island, is situated in the far south-eastern corner of the Gulf of Carpentaria and is rarely visited. The natives, who resent the approach of the white man, have not yet been studied at close quarters. Their number is unknown, though it is estimated at about five hundred. They have no habitations, but sleep on the ground uncovered, except for grass to keep off mosquitos, in all weathers. They wear no clothes and have resisted all attempts to civilize them. Such information as is available concerning them is derived from brief visits of missionaries and others. The island is densely covered with forest, in which the natives take cover when white men approach. They use no cooking or eating utensils, except large sea-shells, in which they carry and store water; smaller shells are used for drinking. Sharpened stones are used for opening oysters. Their food consists of oysters, fish, sharks, turtles, dugong and bush berries. All food is thrown into a fire and left to roast for a time, when it is seized and eaten in the hands. Fish are caught in primitive basket traps sunk in the sea, while turtles, dugong and sharks are speared. Canoes are unknown, but rafts are made of a type known nowhere else. These rafts resemble an elongated V, some measuring up to twelve feet in length and ten feet in width at the broad end. They are made of saplings or logs tied together with bark fibre and vines, the space between the saplings being filled with tightly rammed grass or a 'cement' made of clay, grass and small stones. They are propelled by long paddles resembling cricket bats in shape. The natives are expert in throwing a spear, which ranges in length from six to twelve feet, the heads being spines of stingray tails, bones, fire-toughened wood barbs, or pieces of sharp flint.

Large Flights of Shearwaters

That migration involves enormous mass movements of birds is obvious, but it is seldom that a computation of numbers can be made. On July 12, 1937, Henry E. Parmenter sighted a line of shearwaters off the coast at San Francisco flying northward at from three quarters to a mile off shore. The end of the line to the north could not be seen, so that it was impossible to estimate for how long the birds had been passing; from Point Pedro southwards as far as the eye (aided by a binocular glass) could see, the line was continuous and northbound. (*Condor*, 39, 253; 1937). The observer moved southwards by car keeping the line of birds in view, so that he reached a point 30 miles in a direct line from where the birds had been first seen more than three hours before. If the birds were travelling at about 25 miles per hour (a modest estimate) they must have travelled about 80 miles in that time, so that the flight was at least 110 miles long. Some of the birds were settled upon the water in 'rafts' of varying extent, feeding. A raft one mile long and one eighth mile wide, allowing 10 square feet to a bird, would contain at least 359,000 birds. The author estimates conservatively that the number of birds seen by him and his companion on that occasion was at least 750,000. The species concerned was the sooty shearwater, *Puffinus griseus*.

Habitat and Habits of *Trochus niloticus*

This paper by H. Srinivasa Rao recently published (*Rec. Indian Mus.*, 34, Pt. 1, 1937) deals with an important commercial mollusc. Its range is wide in the Indo-Pacific seas and it is common living among coral reefs and under rocky ledges. The author shows that there has been considerable depletion in the shell population due to continual fishing, the rate of collection per diver per hour having fallen from more than 20 in 1933 to 2–3 in 1935. It is a great wanderer within the limits of the reef surroundings, crawling up from about 7 fathoms on reaching maturity. The shallow waters are thus re-stocked. Its movements are very slow as it seeks food and shelter, the usual food being bottom deposits and fresh algæ. Two types of shell are sometimes regarded as specifically distinct, but they are here attributed to changes of shape probably due to differences of growth at various ages. Sexes are about equal. Females are sexually mature when the shells are about 9 cm. in diameter, males when they are about 6–7 cm. Breeding probably occurs throughout the year, but there are indications that during or immediately after the warm season there is an intensive spell. This species lives to be old and is known to attain ten years.

Swarming and Lunar Periodicity of a *Platynereis*

R. Gopala Aiyer and N. Kesava Panikkar describe interesting swarming habits in a species of *Platynereis*, probably new to science (*Proc. Indian Acad. Sci.*, 5, Sect. B, No. 6; 1937). The account of the heteronereid stage and the lunar periodicity in the swarming habits is submitted with the hope that it will lead to further observations on similar phenomena that may occur also in other localities on the Indian coast. The swarming habits were observed inside Madras harbour for a period of one year. All instances of swarming occurred between 7 and 10 p.m. on days of new moon and a day or two before or after. The time corresponds to the period of maximum high tide for that particular day. On every occasion the sea was calm and there was intense phosphorescence caused by *Noctiluca*. The syllids themselves do not produce light. An interval of three lunar months is observed between successive swarms, and swarming took place during the new moon in the months of March, June and September. No swarming was observed in December although special watch was kept on the day of new moon and the days before and after. The sea was very rough and there was no *Noctiluca*. The authors are of the opinion that the annual swarming has probably ceased with the September display, and occurred again in the March following.

Growth-controlling Substances in Plants

IN a series of preliminary experiments with these substances, Dr. H. L. Pearse has examined the reaction of leafless woody cuttings to treatment with root-forming substances (*Ann. Bot.*, N.S. 2, No. 5, 227; 1938). The experiments were performed on leafless cuttings of *Salix vitellina*, and the synthetic root-forming substance was indole-butyric acid in lanolin paste in one series and indole-butyric acid dissolved in water in the other. Some interesting results were also obtained from partial and complete ringing. It was found that treatment of the basal end of cuttings stimulated root-formation at that end. If, on the other hand, the apical end was treated, root-formation was accelerated throughout the length of the stem, though acceleration was at a maximum at the node nearest the apex and the number of roots decreased from apex to base. Ringing experiments showed that the indole-butyric acid was transported downward in the stem through tissue outside the xylem. It is suggested that the indole-butyric acid itself was the active agent concerned in root formation, and was used up or chemically changed in the process, since when the portion of the base which had been treated was removed, the effect of treatment was eliminated, but if more indole-butyric acid was added, then further response occurred.

Effects of Variations in Atmospheric Carbon Dioxide

ON February 16 a paper was read before the Meteorological Society which deals with a subject that has not occupied the attention of meteorologists very much hitherto, namely, the effect of variations in the amount of carbon dioxide in the atmosphere on the long wave radiation from the atmosphere to the earth, and the consequent effect on temperature. The particular variations with which the author, Mr. G. S. Callendar, is concerned, are those due to fuel combustion, and his subject amounts, therefore, to a study of the effect of fuel combustion on the mean temperature of the atmosphere of the earth, and so on climate. He calculates that the annual addition of carbon dioxide to the atmosphere from this source is [illegible]300 million tons, and by consideration of various other factors that control the amount of free carbon dioxide, such as the solution of the gas into the water of the oceans, arrives at 6 per cent as the calculated increase between 1900 and 1936, resulting from the fuel combustion. An examination of accurate determinations of the amount of carbon dioxide in the atmosphere, made by Brown and Escombe around 1900, and of recent determinations in the eastern United States, suggests that the actual increase and the calculated increase agree very well. The radiation absorption coefficients of carbon dioxide and water vapour are used to show the effect of the former upon the downward radiation of the atmosphere. The observed radiation is due mainly to infra-red absorption by varying amounts of water vapour and from the 3 parts in 10,000 of carbon dioxide normally present in the air. In temperate regions he calculates that with vapour pressure 10 millibars only 5 per cent of the radiation comes from the carbon dioxide, but that in polar regions the proportion is three times as great. A study of the effect of changes in the amount of carbon dioxide on the mean temperature leads to the conclusion that the observed and calculated artificial increase in recent years due to combustion is causing an increase of mean temperature at the rate of 0·003° C. per year. Temperature observations for the last fifty years from different parts of the world are examined and it is claimed that these show an increase at the rate of 0·005° C. a year.

Structure of Rubber

WITH the more extensive data from new X-ray diffraction patterns of stretched rubber an attempt has been made by H. A. Morss, jun. (*J. Amer. Chem. Soc.*, 60, 237; 1938) to find the true unit cell. No really satisfactory solution was reached but some points of interest are described. It appears that the carbon atoms of a molecular chain are not coplanar in stretched rubber. The reason appears to be the large repulsive forces which would have to exist in that configuration. In rotations on the single bonds during stretching and retraction the interatomic forces are probably repulsions in the dominating pairs, the prevailing H—H distances in the closest pairs suggesting repulsive rather than attractive forces. Repulsions give a plausible explanation of the form of the outer part of the stress-strain curve. A structural formula of rubber is proposed. The density of crystalline, stretched rubber as calculated from the unit cell is about 1·00 when the angle between the two independent sets of planes which reflect the two equatorial spots is changed from 90°, which first suggests itself, to 109·5°. This value agrees better with the experimental value 0·96 than the values calculated from other structures.

Production of Cosmic Ray Showers

THE investigation of cosmic ray shower-production by counters only gives an indirect and clumsy analysis of the size of the showers, and M. A. Starr (*Phys. Rev.*, 53, 6; 1938) has examined the production of showers in lead by taking a large number (about 20,000) photographs in a Wilson cloud chamber containing a lead plate. The chamber was released by a coincidence counter arrangement, and the rays are therefore to some extent selected, but it is considered that this selection does not seriously interfere with the statistical conclusions. The frequency of showers of different sizes was studied as a function of the plate thickness. The results are consistent with the cascade theory of showers of Bhabha and Heitler and of Carlson and Oppenheimer. According to these views, energetic electrons lose energy by γ-ray formation and the γ-rays produce electron pairs which again give rise to γ-rays. The average size of a shower increases with the thickness of the lead layer. It is found that about 8 per cent of the electrons striking a 7-mm. lead plate give rise to showers, and that about an equal number of showers are produced by γ-rays. This probability of shower production is much less than expected if all the incident particles observed are electrons obeying the theory, and it appears that more than half the particles are anomalous from this point of view. R. B. Brode and M. A. Starr (*Phys. Rev.*, 53, 3) discuss the ten nuclear disintegrations producing heavily ionizing tracks which were observed in the course of the work. Since these disintegrations coincided in time with the passages of a cosmic ray particle through the counters, they are believed to be due to cosmic rays. They are interpreted as the 'evaporation' of particles due to violent excitation of the nucleus and a sharing of the energy among the nuclear constituents as suggested by Bohr's nuclear theory.

Constitution of the Ionosphere and the Lorentz Polarization Correction

By H. G. Booker and L. V. Berkner

Department of Terrestrial Magnetism, Carnegie Institution of Washington

SOME years ago considerable discussion took place concerning the relation between the constitution of the ionosphere and its refractive index for radio waves. The question at issue was whether the force per unit charge exerted by the electric field of a radio wave upon an elementary charged particle in the ionosphere should be taken simply as the Maxwellian electric intensity E (the Sellmeyer theory), or whether there should be added a contribution $(4\pi/3)P$ (the Lorentz theory), P being the electric moment per unit volume produced by the radio wave in the neighbourhood of the charged particle under consideration. The discussion culminated in a paper by Darwin[1] which is the most exhaustive treatment of the subject so far published. This seemed to point to the conclusion that on theoretical grounds one should expect the Sellmeyer theory to hold good in the ionosphere at radio frequencies.

A clear-cut experiment for deciding between the two theories was first indicated by Ratcliffe[2] and afterwards described in detail by Goubau[3]. The experiment depends on the fact that, for radio waves, the ionosphere is rendered doubly-refracting by the influence of the earth's magnetic field. Free electrons in the ionosphere gyrate around the earth's magnetic field with a frequency of the order of a megacycle per second. For wave-frequencies less than the gyromagnetic frequency there is, under suitable conditions, a clear-cut distinction in the behaviour of the extraordinary wave according to the two theories. The distinction should become apparent when measuring, by the well-known method of vertical radio-sounding of the ionosphere, the variation of echo retardation with wave-frequency below the gyromagnetic frequency in certain regions of the earth. Where the magnetic dip is greater than $\sin^{-1}(1/\sqrt{3}) = 35°$, but less than the value at which vertical propagation in the ionosphere at the wave-frequencies under consideration passes from quasi-transverse to quasi-longitudinal type, the distinction between the two theories is the following. According to the Sellmeyer theory, the virtual height of the extraordinary wave increases to infinity as the wave-frequency increases to the gyromagnetic frequency. However, on account of strong absorption of the extraordinary wave in the immediate neighbourhood of the gyromagnetic frequency, it would be quite impossible to trace the extraordinary wave to an enormous virtual height at a wave-frequency just below the gyromagnetic frequency. On the other hand, according to the Lorentz theory, the virtual height of the extraordinary wave increases to infinity as the wave-frequency increases to a value which we shall call the Lorentz frequency and which is definitely below the gyromagnetic frequency. Moreover, the absorption of the extraordinary wave just below the Lorentz frequency according to the Lorentz theory is less than it is just below the gyromagnetic frequency according to the Sellmeyer theory. In consequence there is a greater possibility of tracing the extraordinary wave to a great virtual height if the Lorentz theory is valid than if the Sellmeyer theory is valid.

At Kensington, Maryland, U.S.A., where the magnetic dip is between 71° and 72°, the Lorentz frequency, neglecting the effect of heavy ions, is about 17 per cent less than the gyromagnetic frequency. Moreover, the reflection coefficient of the extraordinary wave just below the gyromagnetic frequency according to the Sellmeyer theory is about four orders of magnitude less than it is just below the Lorentz frequency according to the Lorentz theory.

The accompanying figure reproduces one of a large number of records which have been obtained over the past year at the Kensington Experimental Station, using the automatic multifrequency equipment developed in this Department. Towards the lower end of the frequency-range these records show echoes the virtual heights of which increase with increase of wave-frequency and tend to infinity as the wave-frequency increases to 1·38 mc./sec. At a frequency slightly below 1·38 mc./sec. it is actually possible to recognize the individuality of successive echoes the wave-frequencies of which differ by known amounts, and to deduce that the virtual height is here increasing with increase of wave-frequency at about a hundred kilometres per kilocycle per second. We interpre these echoes as due to reflection of the extraordinar wave from the F-region of the ionosphere at wav frequencies below the gyromagnetic frequency. T value of the gyromagnetic frequency at ground-level at Kensington is 1·61 mc./sec., and if it decreases with increase of height according to the inverse cube of the distance from the centre of the earth (as it should to a close approximation) it has the value 1·54 mc./sec. at a height of 100 kilometres and 1·44 mc./sec. at 250 kilometres.

One of the striking features of the record here reproduced is that the echo in question can be traced to the enormous virtual height of 1,600 kilometres before it finally fades out. This simple fact makes it obvious from the outset that it is impossible to explain these results in terms of the Sellmeyer theory without drastically reducing, in complete contradiction to accumulated experience, our idea of the order of magnitude of the damping experience by radio waves in the ionosphere.

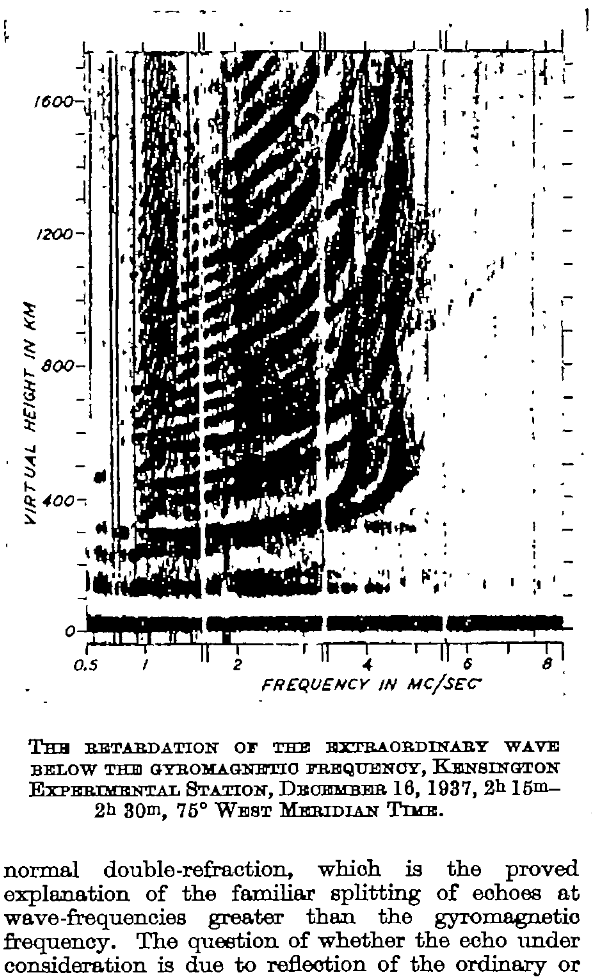
It is important to realize that the large retardation experienced by these echoes is not taking place near the point of reflection. According to either the Sellmeyer or the Lorentz theory, most of the retardation and absorption of the extraordinary wave at these frequencies takes place where the electron density is something like a quarter of that required to reflect the wave. Since the frequencies in question cannot be much above the E-region penetration-frequency for the extraordinary wave, and since there is reason to believe that considerable ionization exists between the E- and F-regions, one might expect on theoretical grounds that most of the retardation and absorption of these echoes would occur in the lower part of the E-region where the ionization density first becomes appreciable. This is confirmed experimentally by the multiple echoes which appear on most of the records. Prominent among these multiples are echoes which, in addition to having travelled up to the F-region and back again, have been reflected back and forth between the E- and F-regions one or more times, suffering partial reflection from the top of the E-region in a manner which is quite common but not fully understood. The consequent additional retardation suffered by these multiple echoes is found to be almost *independent of wave-frequency*. This confirms the expectations that the large retardation experienced by the echoes at wave-frequencies just below 1·38 mc./sec. takes place in the lower part of the E-region. Now we can prove from observations of the penetration-frequencies of the E-region that the value of the gyromagnetic frequency at the level where the waves penetrate the E-region is certainly greater than 1·50 mc./sec.

To interpret these observations in terms of the Sellmeyer theory, it would therefore be necessary to assume that the gyromagnetic frequency, which is proportional to the magnitude of the earth's magnetic field, varies with height above the surface of the earth in the following manner: (1) A decrease from 1·61 mc./sec. at ground-level to 1·38 mc./sec. in the lower part of the E-region, corresponding to an inverse tenth or eleventh power of the distance from the centre of the earth; (2) a sharp increase to a value greater than 1·50 mc./sec. at the level where the waves penetrate the E-region; (3) at greater heights the gyromagnetic frequency could decrease as the inverse cube of the distance from the centre of the earth in agreement with the theory of the earth's magnetic field. In addition it would be necessary to reduce the accepted estimate of the collisional frequency in the lower part of the E-region by more than an order of magnitude and at the same time to explain why the attenuation of radio waves in general is as great as it is. The interpretation of these observations in terms of the Sellmeyer theory would therefore seem to be out of the question.

Qualitatively there seems to be no objection to interpreting the results in terms of the Lorentz theory. To obtain a quantitative interpretation it is necessary to realize that good theoretical reasons exist for believing that considerable numbers of molecular ions are present in the lower part of the E-region and that these can materially affect the value of the Lorentz frequency. In interpreting our results in terms of the Lorentz theory we therefore choose the molecular ion-concentration to have the value which brings the Lorentz frequency to 1·38 mc./sec. The ratio of molecular ion-density to electron-density in the lower part of the E-region turns out to be about ten thousand. Observations of the penetration-frequencies of the E-region show that at the level where the waves penetrate the E-region this ratio has a value of the order of one thousand. Heavy ion-concentrations of these orders of magnitude do not seem unreasonable and are required in order to explain satisfactorily the diurnal variation of terrestrial magnetism.

It is hoped to publish in the near future a detailed discussion of the results and conclusions sketched above.

While this work was being prepared for publication, an account of similar, though apparently less complete, observations was published by Martyn and Munro[4]. But these authors' interpretation of the observations is entirely different from our own, and their conclusion diametrically opposite. The echo which we interpret as due to normal reflection of the extraordinary wave, they interpret as due to an abnormal reflection of the ordinary wave. We are at a loss to understand why Martyn and Munro completely ignore the possibility that splitting of echoes at wave-frequencies less than the gyromagnetic frequency may be due to normal double-refraction, which is the proved explanation of the familiar splitting of echoes at wave-frequencies greater than the gyromagnetic frequency. The question of whether the echo under consideration is due to reflection of the ordinary or extraordinary wave should be settled by observation of its elliptical polarization. It would appear that this has already been done by Farmer and Ratcliffe[5], who found the echo to have the elliptical polarization corresponding to the extraordinary wave in agreement with our interpretation, but who were unable to follow it to wave-frequencies sufficiently high to decide between the Sellmeyer and Lorentz theories.



THE RETARDATION OF THE EXTRAORDINARY WAVE BELOW THE GYROMAGNETIC FREQUENCY, KENSINGTON EXPERIMENTAL STATION, DECEMBER 16, 1937, $2^h\,15^m$–$2^h\,30^m$, 75° WEST MERIDIAN TIME.

Recent Developments of Plant Virus Research

A MEETING of the Royal Society held on March 17 was devoted to discussion of "Recent Developments of Plant Virus Research". The proceedings were opened by Dr. R. N. Salaman, who indicated the lines along which research is progressing. He then dealt in detail with problems arising from the existence of distinct strains within a plant virus, with special reference to potato virus X. Six distinct strains of this virus have been isolated at Cambridge. Wide differences in virulence exist between them, but their relationship is shown by the identity of physical characters and especially by the fact that presence of any one strain in a host prevents reinfection with any other of the six strains. This protective effect implies the existence of a radical common to all X virus strains and distinct from any which may determine virulence. From the differences between the reactions of some strains on potato and tobacco and from the effect of mixing strains with tobacco mosaic he deduced the presence of three or four more radicals. Attention was directed to the possibility of prophylactic inoculation for protection of field crops.

Dr. K. M. Smith discussed "The Ultrafiltration of Plant Viruses". He summarized work on the determination of particle size and stressed the difficulty of interpreting data obtained by filtration of purified virus proteins through graded collodion membranes. Certain plant viruses can only be made to pass membranes of pore size exceeding 400$\mu\mu$, a result attributed to low virus concentration and loss by adsorption. Concentration of viruses leads to reduced filterability. Thus *Lycopersicum* virus 4 and *Nicotiana* virus II in fresh sap have estimated particle diameters of 18–20$\mu\mu$, whilst in purified solutions the values obtained are 80–85$\mu\mu$. With *Nicotiana* virus I the corresponding figures are 22 and 120$\mu\mu$ respectively, results partly explicable on the assumption that in purified and concentrated solutions aggregation of particles takes place. By use of a cataphoresis apparatus the last-named virus can be drawn through a membrane of 13$\mu\mu$ pore diameter. This indicates the existence of ultimate virus units having diameter about 4$\mu\mu$.

Mr. F. C. Bawden described work on purification of crystalline and liquid crystalline virus proteins. From plants infected with tobacco mosaic a nucleoprotein has been isolated, solutions of which have a satiny sheen. When such a solution is slowly concentrated, it becomes viscous, and when shaken the resultant gel breaks up into microscopic needles. A strong solution allowed to stand separates into two liquid layers; the lower and more concentrated is completely birefringent whilst the upper exhibits anisotropy of flow. The difference between the layers has thus been attributed to more perfect orientation of suspended rod-shaped particles in the lower solution. In the host cell the 'X' bodies are not birefringent, but the striate material peculiar to this virus exhibits birefringence along the transverse axis and suggests formation of true virus crystals in the plant, although infected host sap represents only a 0·2–0·3 per cent concentration of virus protein. Great differences may be inferred between the state of virus particles in the host and in purified preparations; the latter are much less infective and show greater anisotropy of flow than a clarified sap of similar concentration. The virus of tomato bushy stunt is also a nucleoprotein, but its purified preparation shows no anisotropy of flow and crystallizes in perfect rhombic dodecahedra.

Prof. J. D. Bernal described the conclusions drawn from X-ray study of the structure of the virus protein molecule. No difference in intramolecular structure can be detected between liquid crystalline proteins isolated from different strains of tobacco mosaic. All have the regular internal crystalline structure characteristic of such proteins as the globulins, and their molecules apparently consist of a number of primary units of dimensions $6 \times 6 \times 6{\cdot}9\mu\mu$. In solutions and gels the particles themselves are also regularly related to each other. The distance between them depends on the concentration of the suspension, but even in a 20 per cent solution an orderly arrangement is maintained. The minimum distance recorded, that in a dried gel, was 132 angstroms, which indicates one dimension of the particle. The corresponding figure for cucumber mosaics 3 and 4 is 135. In plant sap, on the contrary, it was suggested that the virus units of tobacco mosaic are approximately equidimensional, with molecular weight of the order of 200,000 and a size of 120 angstroms.

Dr. MacFarlane dealt with the physical properties of vaccinia, shown by ultracentrifuging to consist of particles of unequal size. Methods were described for determining the density of vaccinia in the undried state, and it was suggested that the vaccinia particle consists of a protein molecule surrounded by an atmosphere of closely bound and orientated water ions. This atmosphere is gradually removed when vaccine is suspended in sucrose solution, while in flocculated virus no water remains. Such a structure implies the impossibility of metabolic reactions on the part of the protein nucleus.

Dr. Findlay summarized the evidence for the existence of strains in animal viruses and pointed out that such strains do not necessarily counter-immunize. Special stress was laid on variation induced by cultivation in unfavourable host tissue, but such altered strains are liable to reversion. Most apparent cases of alteration in properties are probably due to selection from a previously heterogeneous population of strains.

Mrs. Watson discussed the relation of some plant viruses to *Myzus persicæ*. Starvation of the aphis before feeding on the infected plant results in great increase in infectivity, but this effect is lost if the duration of feeding exceeds an optimum period. In the case of *Hyoscyamus* virus 3 and potato virus Y, this period is two minutes; in the case of cucumber mosaic it is fifteen minutes. No direct relationship can be demonstrated between transmissibility by *M. persicæ* and concentration of virus in the plant as estimated by the starch local lesion test.

A general discussion followed, during which Prof. P. A. Murphy stressed the importance of multiplying completely virus-free potato stocks on a commercial scale. Different environments have distinctive virus populations and hence dangers arise from the use of 'masked' plant virus strains as vaccines. Dr. Elford commented on the advisability of reducing adsorption in ultrafiltration work and suggested the use of broth as a medium for re-suspension of purified plant viruses.

Irrigation of Dry Hill Sal Areas in India

THIS subject is discussed by Mr. W. P. M. Warren in the *Indian Forester* of April of last year. Those who have had an acquaintance with the considerable areas of poor open decrepit forest which cover the hills in what was formerly known as Chota Nagpur in the old Bengal Province will be interested to learn of the remarkable experimental work being carried out in a part of this area at Bamiaburu, some twenty miles distant from Chakardharpur on the Bengal-Nagpur Railway. The work so far undertaken has led to results of considerable importance, when it is mentioned that some five sixths of the Bihar forests consist of this worthless type of forest. Of greater value, however, is their apparent opportunity for experimental work on a wider basis in parts of the world where the activities of man are resulting in appalling floods and bad soil erosion.

Briefly, a scheme was commenced in 1933 at Bamiaburu with the object of arresting the run-off water from hillsides by making a system of contour channels. By this means the water percolates down through the soil instead of running to waste. This delayed run-off on an extensive scale would possibly prove a solution for flood problems, by permitting the plain's water, which in any event would be less in quantity, to get away first. As a result of this holding up of the water by the contour channels, remarkable growth is already becoming evident in areas where formerly hollow stagheaded drought-stricken trees prevailed; blanks are filling up with regeneration and the density of stocking is increasing. The cost of the work is low, Rs. 100 per mile only, if dry rubble bunds (walls) for crossing nullahs are made instead of something more expensive. Observations taken during the last year or two have shown that the night temperature in April in the area at present under treatment (height 1,250 ft.) under steady meteorological conditions was equivalent to that experienced at 3,000 ft. in these parts. Humidity and rainfall in May (1936), under disturbed atmospheric conditions were higher than at any other recording station nearby, though its situation and topography were less favourable than at one station. Clouds in the latter half of this month spread each evening over the areas, with the often purely local precipitation of rain. Additional light showers during the day fell only in the area itself, and not outside, and so were not recorded. Mr. Warren does not pretend to be a meteorological expert. No recording station with a similar situation to Bamiaburu exists in the neighbouring areas, and he had not the advantage himself of proper equipment. He therefore only summarizes actual experiences and records obtained. It is too early to claim too much from this remarkable experiment. But to those formerly acquainted with this, in April and May, torrid region, the results so far attained appear to open great possibilities.

That this contour-channel method is not a new idea, in India at least, is shown in an article by Dr. R. M. Gorrie, in the May issue of the *Indian Forester*, on that evergreen theme, the erosion in the Pabbi Hills in the Gujrat District in the Punjab. This problem is more than half a century old, the country having been taken over by the British in 1857, some attempts at regulating the grazing on this arid and already heavily eroded mass of foothills rising out of the plain being made about 1877. At this period the erosion was considered in connexion with the North Western Railway line. In the early 1880's reclamation and protection work were taken in hand by the late J. H. Lace. One of the methods introduced by Lace was trenching dug along the contours of steep slopes to catch and hold water for the use of tree seedlings on the berm.

Lace's work was successful, but Government soon let it drop, and the subsequent history of the Pabbi is depressing reading. What has forced the Pabbi erosion question to a head in modern times is the building of the Upper Jhelum Canal. This work is being affected to a serious extent by the enormous masses of silt brought down in the sudden floods, and considerable sums of money have had to be spent on protective works to the canal system from this cause alone.

Scientific Tests of a Vaudeville Telepathist

BULLETIN 3 of the University of London Council for Psychical Investigation consists of a detailed study by S. G. Soal of the hyper-acuity of the senses that is made use of by Josef Kraus ("Marion"), either consciously or unconsciously, in producing his demonstrations of telepathy and clairvoyance. The interest of this report is enhanced by the fact that it is the first scientific research into this subject, and it need scarcely be pointed out that the precautions that have to be taken when human beings are the material of the experiment far exceed those necessary in other branches of science. As an exposition of these precautionary measures alone, the Bulletin is quite outstanding and should be carefully studied by everyone interested in psychical research. Incidentally, the facts disclosed in this research throw very grave doubt on the supposed proofs of telepathy and clairvoyance that have recently received considerable publicity, and in particular those of Dr. J. B. Rhine in the United States.

In Section 1, a statistical study of the results of experiment shows that Marion can rapidly locate small objects that have been hidden by a small audience who know the hiding-place and whose involuntary movements he is able to observe. Similarly, he can determine an imaginary hiding-place concentrated on by the audience when no actual object is hidden. But he cannot improve on chance results if the audience is screened from his view, or if no one in the room is consciously aware of the hiding-place. This indicates that he gets visual indications of small unconscious movements by one or more persons in the audience.

In another series of experiments, Marion exhibited a power superior to that of Cumberlandism or muscle-reading by finding hidden objects when followed by a single person who knew the hiding-place. Progressive covering up of this agent by a wooden box showed that Marion could still succeed even when he could see no more than the agent's feet. If the agent was totally covered and wheeled round the room, failure ensued. In this case slight changes in the movements of walking appear to be the principal *indicia*. This result clearly indicates that in any telepathic experiment the agent should not be visible to the percipient.

In Section 2, Marion's power of recognizing cards which he had previously handled, when mixed in a new pack, is studied, and it is shown that this is probably due to tactual discrimination of a high order. His departure abroad prevented experiments to see if he could emulate the blind osteopath, Captain Lowry, by distinguishing the pips on a playing-card by sense of touch alone.

Further statistical and other tests in telepathy and clairvoyance are described in Section 3; but no evidence was provided of any faculty for reading the contents of sealed envelopes or of divining numbers thought of by members of an audience. Marion's claims as regards graphology and psychometry also seem to be without foundation.

Transatlantic Steam Navigation a Century Ago

JUST when the S.S. *Sirius* and the S.S. *Great Western* were being advertised to sail on their first passages to New York, and on the day, March 31, 1838, the *Great Western* left the Thames for the Severn, preparatory to starting on her voyage on April 8, the *Athenæum* published an article running to four pages under the title "Atlantic Steam Navigation". This was one of several articles in the same journal all of which were written with a good knowledge of the subject and in an unprejudiced manner. From the article which appeared in the issue of March 31, the following passages are taken:

"There is really no mistake then in this long talked of project of navigating the Atlantic Ocean by steam. There is no doubt, that is, of the existence of the intention to make the attempt, and to give the experiment, as such, a fair trial. Nor is the intention entertained (like many innovations sometimes more ingenious than will bear much examination) by an irresponsible party, or by one party alone, as we shall presently show. The whole commercial community, at least of our own country, and we may add of the United States, are alive to its interest. In Liverpool, New York and the 'Great Metropolis'—the three depots of the mercantile navigation of Christendom . . . the work goes bravely on. The *Sirius* is absolutely getting under weigh, while we write this paragraph, for America New York, via Cork! The buzz of excitement yesterday reached even the secluded walls of our own study. We rushed down to Blackwall pell-mell, in an omnibus, like all the rest to see not the *Sirius* but the *Great Western*, which the papers have told us so much about for a month past. . . . Groups of nobility and gentry, with his Grace of Wellington at their head, figured in the cabin album; and we met as we came back, the Lord Mayor with his state carriage and four footmen rolling in gold, dashing down to Blackwall to get a last glimpse; all in pursuit, in a word, of the great animals of the day—the steamers now starting for the other side of the Atlantic.

"There is no mistake, then, we repeat, as to the trial of the experiment."

The writer of the article then went on to deal with the *Sirius*, the *Great Western*, the companies, the construction of the *British Queen* at Limehouse, the charges to be made for passengers and letters, the attitude of the Liverpool shipowners and other matters. "Our space," he concluded, "is now small for discussing anew the policy or subsequent prospects of this scheme. We consider it, however, in that view, a subject of very considerable importance, as well as of the most curious and teeming interest. If sustained, there can be no doubt of its vast advantage in *speed*. . . . For the mails, for the immense and vastly increasing correspondence between the two countries, for all personal intercommunication of mercantile men . . . this is a vital and conclusive point. We must count also on an increase in travelling, if not of trade. . . .

"We think the sum of it, for the present, may be taken thus:—the practicability of steam will be established at once. Its speed and its certainty will induce interests, enough for its maintenance, to a greater or lesser extent to support it. All correspondence will be conveyed by it; all mercantile travel and some goods. Most passengers may be shy of it for a time—many for a long time (as some are of railroads still); accidents will happen of course; still the scheme will go on to maturity. Of its influence on other and far greater interests than yet alluded to, we cannot now speak. This is a scheme not to be hastily treated. It is one, too, which may be deferred awhile. All eyes now are turned on the "*commencement* of the end". We may yet discuss with improved data, the *end* of such a beginning."

The *Great Western*, the first steam vessel designed for the Atlantic passage, it may be added, was 212 ft. between perpendiculars, 35 ft. wide inside the paddle boxes and on a draught of 16 ft. 8 in. displaced 2,300 tons. Built of wood, she was strengthened in an elaborate manner by diagonal trussing of wood and iron and was copper sheathed. She had four boilers designed to work at 5 lb. pressure and her engines developed about 750 horse-power. Her machinery weighed nearly 400 tons and she stowed about 600 tons of coal. She left Blackwall early on March 31, 1838, and when she was between Gravesend and Southend a fire broke out around the base of the funnel which threatened to spread to the ship. The fire, however, was got under and the ship eventually left the Severn on her maiden voyage on April 8.

University Events

Cambridge.—At Trinity College, Prof. W. L. Bragg, Cavendish professor of experimental physics and former director of the National Physical Laboratory, has been elected into a professoral fellowship.

At King's College, J. W. S. Pringle and K. H. Harrison have been elected into fellowships. Mr. Pringle was educated at Winchester College, was placed in the first class of both parts of the Natural Sciences Tripos, was awarded the Amy Mary Preston Read scholarship in 1937 and appointed a University demonstrator in zoology. Mr. Harrison was educated at Bootham School, placed in the first class in both parts of the Natural Sciences Tripos and awarded the Benn W. Levy Research Studentship in biochemistry in 1936.

Leeds.—Mr. W. E. Adams has been appointed lecturer in histology and will take up his duties at the beginning of next session.

Oxford.—The Rolleston Memorial Prize of the value of about £100 is awarded every two years for original research in animal and vegetable morphology, physiology and pathology, or anthropology. Memoirs already published may be submitted and graduates of Oxford or Cambridge or research students are eligible. Further information can be obtained from the Registrar of the University, Oxford, to whom the memoirs should be sent before March 31.

The next award of the Radcliffe Prize, which is of the value of £50, will be made in March 1939. It is awarded for research in any branch of medical science and is open to all graduates of the University who are proceeding to a medical degree at Oxford. Further information can be obtained from the Secretary of the Faculties, University Registry, Oxford.

Societies and Academies

Paris

Academy of Sciences, January 24 (*C.R.*, 206, 221–288).

Jean Cabannes and Jean Dufay: The yellow radiation of the night sky. Utilizing numerous photographs made at Montpellier, the wave-length of the yellow line is found to be 5894 ± 1 A. The possibility of this line being produced by the emission of sodium atoms in the upper atmosphere is considered.

Charles Eugène Guye: Rectification of the note of January 4 on the possibility of verifying experimentally the relation $\nu = \nu_0 \sqrt{1-\beta^2}$ of limited relativity.

Raphaël Salem: The convergence *presque partout* of certain trigonometrical series.

Paul Lévy: The variation of the maximum of a function.

Lucien Hibbert: The solution of algebraical equations of the form $z^n = z - a$.

Carlos Biggeri: Some theorems on the peripheral singularities of Taylor's series.

Albert Métral and François Raymond: A method of measuring the resistance caused by the air on a railway train.

Adolphe Festraets: The Stroobant (star) stream.

Bernard Kwal: The indetermination of electromagnetic potentials.

Ouang Te-Tchao: The spectrum of mobilities of the large ions.

Noel Felici: The equilibrium of supra-conductors.

Robert Pinoir: A new method of stabilization of the anodic current of electronic valves with respect to variations of the plate potential.

Michel Cymboliste: The relations between the state of the surface of electrolytic chromium, its structure and its mechanical properties.

F. Redslob and H. Forestier: Study of the reactions of the formation of the ferrites of tin and cadmium.

Georges Costeanu and Paul Renaud: The actions of water, hydrogen sulphide and iodine on sensitive surfaces.

André Chretien and Gustave Oechsel: The use of acetyl chloride as a chlorination agent in inorganic chemistry. Acetyl chloride reacts with various metallic oxides (UO_3, V_2O_5, MnO_2). The apparatus used for the isolation and purification of the products is described and illustrated.

Mlle. Yvonne Garreau: The action of thiochronic acid and of 2·5-dichlorhydroquinone-3·6-disulphonic acid on the primary amines. Constitution of the latter acid and of euthiochronic acid.

Georges Laude: The influence of some factors on the formation of ammonia by boiling proteins with alkaline solutions of potash.

Albert Michel-Lévy and Jean Wyart: The utilization of the high temperatures and high pressures realized in the detonation of explosives for the artificial reproduction of minerals: zincite and willemite. Starting with a precipitate of amorphous silica in a brass container, the detonation of an explosive gives crystallized willemite.

Marcel Chichery: The stratigraphy of the Dinantian formations of the Ardoisière basin, near Vichy (Allier).

Georges Choubert: The Dogger of the Hauts-Plateaux and of the middle Moulouya.

Hubert Garrigue: A study of the variations of temperature of the free air at the edge of an aeroplane.

Roger Faillettaz: Recording atmospherics and storm predictions.

Maurice Burgaud: Magnetic observations in China. Tabulated results from 38 stations in China, reduced to January 1, 1937.

Frédéric Marie Bergounioux: The discovery of a fossil tortoise in the Permian of Saint-Christophe (Aveyron).

André Sarazin: The nuclear evolution of the basidia and of the basidiospores in *Agaricus campestris*.

René Souèges: The embryogeny of the Campanulaceæ. The development of the embryo in *Jasione montana*.

Raymond Cahen and E. Moisset de Espanès: The cardio-vascular effects of the fluid extract of *Gelsemium sempervirens*.

Louis Gallien: The action of dihydrofolliculine benzoate in the differentiation of sex in *Rana temporaria*.

Albert Vandel: The action of X-rays on the terrestrial Isopod *Trichoniscus (Spiloniscus) provisorius*.

Dublin

Royal Dublin Society, January 25.

V. C. Barry: The preparation, properties, and mode of occurrence of laminarin.

J. Carroll: Mineral oils as insecticides. An outline of the extent to which kerosene has been used in the past and of recent research on the use as insecticides of other fractions and grades of mineral oil. A full account is given of the utilization of lubricating oil emulsions, miscible oils, white oil emulsions, and combined tar-distillate and mineral oil sprays. Combination mineral oil and fungicide sprays are discussed, with suggestions as to promising lines for further research.

O. Roberts and J. Doyle: The *p*H of conifer leaves in relation to systematy. Individual variations in *p*H are small. Seasonal variations, though also small, seem definitely related to seasonal metabolic changes. From the examination of more than ninety species it appears that there is a strong tendency in conifers for natural affinity to be expressed in similarities of metabolism, which are shown by correspondence, often very definite, of the *p*H range of the related groups.

Amsterdam

Royal Academy (*Proc.*, 41, No. 1, Jan. 1938).

H. Y. Jordan and J. Guittart: Regulation of the breathing of *Astacus fluviatilis*. The river crawfish reacts by hyperventilation to lack of oxygen as proprioceptive stimulus.

H. A. Kramers: Use of 'grand ensembles' in statistics. Remarks on the application of Gibbs's methods in classical and quantum statistics.

J. G. van der Corput: Two, three or four primes (2).

P. Erdös: Additive properties of squares of primes.

C. S. Meyer: An integral representation of the Whittaker function.

J. F. Koksma: Metric considerations on the approximation of real numbers.

G. C. Hirsch and J. W. Sluiter: Change in the structure and shape of the Golgi bodies in the primary yolk of the hen's egg and the 'system theory' of the Golgi bodies.

P. C. Flu: Investigation into the phage content of phage-containing globulin repeatedly precipitated by means of ammonium sulphate.

P. J. Haringhuizen and D. A. Was: A research on thin layers of tin and other metals. (4) Further investigation on the corrosion by oils. Experiments on the corrosion of iron and cadmium by lubricating oils, and of tin, iron and copper by olive oil and salad oil.

Cracow

Polish Academy of Science and Letters, January 10.

W. Jacyna, L. Malis and A. Obnorsky: Critical remarks on the thermodynamic scale below 1° K. The method used by Kürti, Lainé and Simon is considered incorrect. A thermomagnetic equation of sufficient exactness is indispensable.

T. Banachiewicz: Control relations for the multiplication of Cracovians.

J. Zawadzki and Mlle. A. Ulinska: The dissociation of zinc carbonate and the action of carbon dioxide upon zinc oxide. Contribution to the mechanism of reactions of the type $A_{sol} = B_{sol} + C_{gas}$.

J. Tokarski: The petrographic analysis of the tufas of Berestowiec.

J. St. Mikulski: Experimental researches on the thermal ecology of eggs in the course of development of some tail-less Amphibians (*Rana, Bufo, Pelobates*).

Mlle. J. Ackermann: Experimental histochemical researches on the metabolism of lecithin in the animal organism. The influence of the ingestion of lecithin on the lipid content in the liver.

S. Skowron and Z. Wicinski: Factors determining the duration of the yellow bodies.

Moscow

Academy of Sciences (*C.R.*, 17, No. 8, 1937).

P. P. Dobronravin: A possible interpretation of the new system of the TiO bands in the infra-red.

F. M. Šemiakin and P. F. Mikhalev: Probable mechanism of the formation of periodic ice streaks in the course of soil freezing, with reference to the problem of permanently frozen subsoil.

B. Deriagin: A device for the investigation of the sensitivity of eye to the ultra-short illumination.

N. S. Kurnakov, I. B. Feigelson and A. G. Bergman: Cyclochronograms of salt lakes. Lake Elton (1932–1936).

E. V. Zmačinskij: Reaction for the differentiation of fruit sugar from grape sugar.

M. P. Volarovič and L. I. Korčemkin: Connexion between the viscosity of molten rocks and the acidity coefficients according to F. J. Loewinson-Lessing.

M. P. Volarovič and A. A. Leontjeva: Investigations on the viscosity of obsidians, with reference to the problem of genesis of pumice stone.

D. Kostoff: Size of *Nicotiana rustica* L. × *Nicotiana tabacum* L. hybrid embryos and hybrids in respect to their parents.

G. H. Molotkovskij: A porometer for investigations under natural conditions.

G. M. Psarev: Influence of the alternation of day and night on the nature of the variation in the duration of the various phases of development in soya.

M. I. Menšikov: New data on the distribution of fishes in the basin of the Irtysh.

A. A. Voitkevič: Morphogenetic activity of various parts of hypophysis. (10) The mechanism of the action of the basophile elements of the anterior hypophysis lobes on the feathers of birds.

C.R., 17, No. 9, 1937.

A. Gelfond: A generalization of the inequality of Minkovski.

S. Sobolev: A class of integro-differential equations with several independent variables.

N. Achyeser: The best approximation in a class of constant periodic functions.

A. Markoff: Existence of an invariant integral.

S. I. Wawilow: Nature of the elementary sources of light and the interference phenomena.

A. I. Alichanian and A. S. Zavelskij: (1) The low-energy region of the β-spectrum of radium E. (2) The low-energy region of α-spectra of thorium C'' and thorium B.

I. Koukles and N. Piskounov : Tautochromic vibrations in conservative and in non-conservative systems.

M. M. Katznelson and D. A. Brodsky : Hexahydro-benzil-barbituric acids.

K. I. Makov : Cimmerian deposits in the Skadovsk district, Ukrainian S.S.R.

N. N. Konstantinov : Some interspecific crossings in the genus *Gossypium*.

V. A. Hižniak : Wheat-quitch amphidiploids.

F. Ukradyga and A. Oleksijuk : Nutritive media for sugar beet in sand and water cultures.

V. G. Aleksandrov and O. G. Aleksandrova : Mosaic of wheat endosperm.

N. S. Petinov and P. S. Belikov : Continuous supply of plants with water as an indispensable condition of high yields.

B. I. Balinskij : Production of supernumerary balancers in deficiency experiments in *Triton* embryos.

Washington, D.C.

National Academy of Sciences (*Proc.*, 24, 1–52, Jan. 15).

S. Gaposchkin : Asymmetry of light curves in the 'great sequence' as a function of frequency of period.

B. J. Bok and E. M. Lindsay : Stellar distribution in the vicinity of a southern galactic window.

E. H. Myers : Present state of our knowledge concerning the life-cycle of the Foraminifera. For many of these organisms, now extensively used in problems of stratigraphical geology and as guide fossils in petroleum geology, the life-cycle consists of an orderly succession of sexual and asexual phases, leading to dimorphism of the test or shell.

G. A. Miller : Groups having a maximum number set of independent generators.

M. Richardson : Special homology groups.

H. S. Uhler : Log π and other basic constants. The fundamental formula underlying the work is a formula for π given by Ramanujan. By its use, with machine calculation, values are given for $\frac{1}{2}\log_{10} 2\pi$, $\log_e \pi$, $\log_{10} \pi$, $\log_{10} 2$, $\log_{10} 3$, $\log_{10} 5$, $\log_{10} 7$, $\log_e 17$, $\log_1 17$, $\log_e 71$, $\log_{10} 71$, $\log_e 113$, $\log_{10} 113$, $1/\pi$ and π^2, most of them to more than 200 places of decimals.

A. Fialkow : Einstein spaces in a space of constant curvature.

E. Kasner and J. De Cicco : Classification of element transformations by means of isogonal and equi-tangential series.

J. W. Calkin : Abstract self-adjoint boundary conditions.

J. van Overbeek : A simplified method for auxin extraction. The auxin was extracted from uncrushed material with ether alone, and its concentration is expressed in terms of hetero-auxin (indole-3-acetic acid).

E. B. Fred, P. W. Wilson and O. Wyss : Light intensity and the nitrogen hunger period in the Manchu soybean. Plants exposed at an early stage to intense sunlight are unable to fix atmospheric nitrogen, due apparently to high carbohydrate-nitrogen ratio. By shading a plant for a few days or by addition of combined nitrogen (calcium nitrate), it responded quickly, the leaves becoming green and nitrogen fixation established, due apparently to the change effected in the carbohydrate-nitrogen ratio.

Forthcoming Events

Monday, March 28

Royal Geographical Society, at 5.30.—Film of "Australian Aboriginal Tribes", lent by the British Museum.

Royal Society of Arts, at 8.—Dr. M. A. H. Tincker : "The Growth of Plants in Relation to Cultivation" (Cantor Lectures. Succeeding lectures on April 4 and 11).

Thursday, March 31

British Society for International Bibliography (at the Science Museum), at 5.15.—B. V. J. Brajnikoff : "Abstracting Russian Literature".

Friday, April 1.

Royal Institution, at 9.—Sir Frederick Keeble, F.R.S. : "Humphry Davy, Farmer."

Chemical Society, March 31–April 1.—Annual General Meeting to be held in Manchester.

April 1.—Prof. G. Barger, F.R.S. : Pictet Memorial Lecture.

British Psychological Society, March 31–April 4.—Extended General Meeting to be held in the University of St. Andrews.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned :

Head of the Chemistry Department of the Coventry Technical College—The Director of Education, Council House, Coventry (March 26).

Junior Maintenance Engineers at the B.B.C.—The Engineering Establishment Officer, B.B.C., Broadcasting House, London, W.1 (March 29).

Plant Pathologist in the Department of Agriculture for Scotland —The Secretary (Establishment Branch), 29 St. Andrew Square, Edinburgh, 2 (March 31).

Chemist, Physicists, Bacteriologist and Junior Chemist to the Wool Industries Research Association, Torridon, Leeds, 6—The Secretary (March 31).

Scientific Officers and Junior Scientific Officers in the Department of Scientific Research and Experiment, Admiralty—The Secretary of the Admiralty (C.E. Branch) (April 2).

Assistant (Grade III—chemistry) in the Department of Scientific Research and Experiment, Admiralty—The Secretary of the Admiralty (C.E. Branch) (April 2).

Assistants (Grades I and II—mathematics) in the Department of Scientific Research and Experiment, Admiralty—The Secretary of the Admiralty (C.E. Branch) (April 2).

Physicist in the Radon Department, St. Bartholomew's Hospital, E.C.1—The Acting Clerk to the Governors (April 4).

Junior Scientific Officer in the Wood Chemistry Section of the Forest Products Research Laboratory, Princes Risborough, Aylesbury, Bucks—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (April 9).

Lecturer in Mechanical and Marine Engineering in the City Technical College, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool, 1 (April 11).

Professor of Chemistry in the University of Sheffield—The Registrar (April 23).

Demonstrator in Mathematics in the Imperial College of Science, Prince Consort Road, South Kensington, S.W.7—The Secretary (April 26).

Assistant Lecturer in Social Psychology in the London School of Economics—The Secretary, Houghton Street, Aldwych, W.C.2 (April 30).

Leverhulme Foundation Fellow and Lecturer in Physics in the University of Liverpool—The Registrar (May 1).

Professor of Chemistry in the Indian Institute of Science, Bangalore—The Registrar (June 1).

Chief Mechanical Engineer and Temporary Chemists in the Royal Naval Cordite Factory, Holton Heath, Dorset—The Secretary of the Admiralty (C.E. Branch, II), London, S.W.1.

Lecturer in Mechanical Engineering in the Borough Polytechnic, Borough Road, S.E.1—The Principal.

Lecturer in Air-Conditioning in the Borough Polytechnic Borough Road, S E.1—The Principal.

Vol. 141 SATURDAY, APRIL 2, 1938 No. 3570

Civil Aviation in Great Britain

THROUGHOUT the post-War period, the development of civil aviation in Great Britain as in other countries has been warped by military demands. The report on the Economics of Air Transport in Europe submitted by M. Henri Bouché to the Air Transport Co-operation Committee of the League of Nations in 1935 revealed not only the uneconomic position of civil aviation in Europe generally, but also the way in which national prejudices or military arguments have deprived civil aviation of the freedom which would enable it to reap the advantages inherent in its potentially greater speed as compared with surface transport. In observations on the recently issued report of the Committee of Inquiry into Civil Aviation, which was under the chairmanship of Lord Cadman, the Government has admitted that the unprecedented effort of the Air Ministry and the aircraft industry of the last two years in the military sphere have accentuated the neglect of civil attention, although it is now thought to be possible to give further assistance to civil aviation and to improve its organization.

The present report (Cmd. 5685. London : H M. Stationery Office, 1938. 1*s*. 6*d*. net) is the outcome of a storm of Parliamentary criticism of British civil aviation in November last, which indeed led to the reconstruction of the membership of the original committee, and the contents of the report confirm the soundness and pertinence of much of that Parliamentary criticism. No one who reads the report or who followed the subsequent debate in the House of Commons can be in doubt as to the room or need for further and strenuous efforts in the field of civil aviation and world air transport, and the report should stimulate both interest and constructive criticism in this field. The need for the continuous pressure of informed opinion is sufficiently illustrated by the reference in the report to the failure to give full effect to the recommendations of the Maybury Committee on the development of civil aviation in the United Kingdom, although their acceptance by the Government was announced more than a year ago.

It should not, of course, be overlooked that the Government policy of concentrating on the development of Empire routes, which constitute 90 per cent of the total mileage operated by Imperial Airways Ltd., has to a large extent been fully justified, and that such services have advanced much further towards financial autonomy than the great majority of Continental routes, which, as was shown by M. Henri Bouché and is pointed out again in this report, are much more heavily subsidized. So, too, the report finds no evidence that Imperial Airways' services are less safe than those of any foreign company or that traffic considerations are allowed to outweigh prudence.

The report emphasizes the necessity of closely associating and co-ordinating four elements in civil air transport if successful development is to be assured. There is first the machinery of Government, covering such matters as the initiation of policy, consideration of the international implications of civil aviation, stimulating the development of aircraft, and controls required in the interests of safety. Then there is the aircraft operator, who will give practical effect to Government policy by developing air transport with energy and foresight. Thirdly, there is the aircraft constructor, and lastly the provision of essential ground organization.

The Committee recognizes that the military aspect of aviation cannot fundamentally be separated from the civil aspect, and emphasizes the necessity for much more virility in the initiation of policy and foresight in planning. The stimulation of research and design and the production of civil aircraft, as well as the encouragement of suitable organization of the aircraft industry, devolve upon the Secretary of State. Continuity in directing the policy of aircraft research, development and production is essential, and the Committee trenchantly criticizes the present system of expecting a military officer without previous knowledge and experience of such matters and holding office for a limited term to deal effectively with the situation.

The recommendation for the creation of a post of Permanent Under-Secretary of State for Air to assume control of this Department has already been accepted by the Government, as have further recommendations for the appointment of a Deputy Director of Civil Aviation and a Director of Civil Research and Production, and for strengthening the technical staff concerned with research and development. The Government, however, has not accepted the recommendation of the Committee that the functions of the Member for Research and Development on the Air Council, and also that part of the Department administered by the Air Member for Supply and Organization which deals with the production of aircraft, should be transferred to the Permanent Under-Secretary of State, as it is considered that such changes would seriously interrupt the work of the Service side of the Air Ministry.

In its observations on this question, the Government points out that the Department of Research and Development is already an extensive organization, largely civilian and permanent, the Director of Scientific Research being a permanent officer and a scientific worker of high repute. The Department is in close touch with other Government research establishments, with universities and with private firms, and its research and experimental establishments provide testing stations and a central laboratory for theoretical research. The Government contention that research and development on the Service side are in fact continuous and progressive, and that much of this work is of immediate value and available to makers of civil aircraft, is, however, not disputed by the Committee. Its contention is that, in the past, most of the research undertaken by the Air Ministry has had a military bias, and the reorganization recommended is intended to ensure that civil research work is given due prominence in future.

The tenor of the Government observations on the subject of research is accordingly less reassuring than might be desired, and the Prime Minister's silence on the subject in the debate is in itself disturbing. It is suggested, in fact, that instead of defence requirements drawing on the general body of scientific knowledge and applying it to the particular problems of defence, supplementing it by further investigation as required, in the field of aviation this policy is to be reversed and the trend of development dictated by Service requirements. This very policy has restricted and warped the whole development of civil aviation since the War, and it is optimistic to expect much improvement until the resources available for research and development in aviation are administered by those possessing not only the essential technical and administrative qualities, but are also trained to view the subject as a whole and not primarily in respect of Service requirements.

This is indeed the main point in the Committee's contention that the direction of aircraft research, development and production should be transferred from a military to a civil officer, not necessarily a technician, but possessing high ability, energy and proved capacity for organization. It is further supported by the reference to specific problems of research, such as the icing problem, with which two appendixes to the report deal in some detail. The prevention of ice formation is indeed a composite problem affecting the engines, airscrews, instruments, wireless equipment and the air frame itself, and the report insists that research into this problem should be prosecuted with the utmost vigour.

Other research problems to which the report directs special attention include such matters as pressure cabins, automatic blind landing equipment, anti-static electricity devices and the application of wireless to aviation purposes, in all of which evidence was submitted that Great Britain is not keeping pace with the United States of America, while special attention to lines of research which would make flying safer is also urged. It is indeed pointed out that unless a limit is soon put to the size of aerodromes, considerations of cost may prove a serious handicap to further progress, and on this ground alone a reduction in the landing speed of air liners without impairing performance in other respects is desirable.

Scientific workers can scarcely fail to be keenly interested in these technical problems as well as in the recommendations relating to policy and reorganization intended to give civil aviation some of the freedom of development of which it has been deprived largely by defence considerations. They will, however, be equally interested in the comments of the report on staff questions. Here the report is perhaps unduly reticent, and its criticism is implied rather than openly expressed. That it should be necessary for a report of this type to make the recommendation that personal contact between employer and employee in air transport should be supplemented by collective representation is a serious reflection on the management concerned, and its significance cannot be appreciated without regard to the great advance in dealing with staff matters characterizing large-scale progressive industry in recent years. The fact that the Committee should find it necessary to recommend that dividends should be restricted to the limits usually associated with public utility companies—a principle with which the Prime Minister announced his sympathy—further indicates how far the managements of Imperial Airways or British Airways Ltd. has lagged behind the best practice and principles of modern management.

There can be no two opinions that the inquiry instituted has been thoroughly justified, and if the recommendations of the report are implemented there is reason to believe that civil aviation in Great Britain may be liberated from some of its shackles. None the less, it is clear from the Government observations that defence considerations remain the dominant factor, and it should not be forgotten that civil aviation can only gain its true freedom in the international sphere. Fundamentally, moreover, the report is a telling indictment of the management of the industry, and adds yet one more warning to others in the past of the dangers to the community of allowing control to remain in the hands of those who are incompetent to take long-range and progressive views, or to assess accurately and sympathetically the technical and human as well as the financial issues involved. In these days, when the resources at the disposal of scientific management are so vast and accessible, there is less excuse than ever for maladministration and failure to ensure that those in control possess the administrative capacity for their task is more likely than any other factor to involve the downfall of social or industrial institutions to-day.

Petroleum Technology

The Science of Petroleum:
a Comprehensive Treatise of the Principles and Practice of the Production, Refining, Transport and Distribution of Mineral Oil. Editors: Dr. A. E. Dunstan, Prof. A. W. Nash, Dr. Benjamin T. Brooks, Sir Henry Tizard. Vol. 1. Pp. xxvi + 836. Vol. 2. Pp. xvi + 837–1670. Vol. 3. Pp. xvi + 1671–2386. Vol. 4. Pp. xvi + 2387–3192. (London: New York and Toronto: Oxford University Press, 1938.) 4 vols., £15 15*s.* 0*d.* net.

EVEN in an age of industrial achievement the economic efficiency of the petroleum industry is outstanding. In particular, its products have been progressively and rapidly adjusted to the ever-changing requirements of a world largely based for its mechanized civilization upon the internal combustion engine. What is still more striking is that many of these adjustments have been made in advance of the engine-builder's demand for them. The designer has been encouraged in effect to produce more and more efficient units because of the special fuels and lubricants waiting to his hand. He now sets no limits to his requirements in this direction, for he knows from experience that the oil industry will serve him to the fullest extent of its resources even if it means scrapping (as often happens) the highly successful plant and process of the previous day.

This spirit of deliberate self-modernization is evident throughout the oil world. It is significant that the biggest technical advances and productive successes in the search for petroleum by geophysical means have been made at a time when visible reserves of oil are greater than ever in the past and when production in many quarters has had to be artificially restrained. It is equally worthy of mark at the other end of the scale that chief encouragement of the synthetic production of oil has come from the large petroleum undertakings, and not from the coal or similar interests, which might be expected most directly to benefit.

The great research stations of the petroleum industry and its modern refineries; its geophysical surveying, high-pressure drilling and thousand-mile pipe lines; its tanker fleets, its distribution organization and its resolute development of a new synthetic chemistry, all reflect a standard of technical and administrative attainment which it is difficult to parallel. There is, too, an atmosphere of audacity about some of its doings which compels recognition of the industry's aliveness and youthfulness. That is probably the answer to many things in the petroleum industry. It is young, it is successful. It has money, it has vision. Through these it has been able to attract to itself men of high capacity and to reward them. As a result the last two decades have seen within the industry's wide range of interests a complete departure from all empirical methods and a dependence upon organized development and control which can only be apprehended with difficulty even by those directly concerned with oil in one way or another.

It follows that the scientific basis of the exploitation of petroleum must be very wide. How wide can be partly judged by a statistical description of the work under review.

This work consists of four quarto volumes weighing approximately two stone and containing more than 3,000 pages. It has been produced by the co-operative efforts of four editors, twenty-four associate editors, 316 contributors and many secretaries, index-compilers and general assistants. It is divided into five parts and 44 sections. Each section contains a sufficient number of papers from specialist contributors to cover all aspects of a particular subject without loss of the individuality arising from separate authorship. The subjects range from nomenclature to shale oil. They cover the origin of petroleum, its distribution, exploration, winning and transportation; physical and chemical data and testing; refinery processing of all kinds; cracking, re-forming and hydrogenation; manufacturing materials, instrumentation and use of commodities; direct products and their utilization; synthetic derivatives and bitumen.

The intrepidity involved in undertaking this work can only be matched by the tenacity of purpose which has brought it to successful issue. Dr. Dunstan, Prof. Nash, Dr. Brooks and Sir Henry Tizard are severally to be congratulated on the completion of a task which they must at times have felt to be endless. To them and to the publishers are due the sincere thanks of all interested in the "principles and practice of the production and refining of mineral oil". They have done what they set out to do and have produced a "Comprehensive Treatise". The work is not merely a landmark in the history of the literature of petroleum—it is a record of knowledge and achievement which must inevitably form the basis of all future writings on similar lines, whether they be digest or dissertation. Moreover, by being collated in the form of groups of individual papers, its own supplementation should be fairly straightforward. It is obvious that arrangements for keeping the treatise up to date will have to be made right away.

The list of contributors discloses the fact that as to four fifths of the work they are drawn about equally from Great Britain and the United States. This is flattering to the British position in the oil world, and is accounted for by the preponderatingly British editorship. Although there are missing in consequence a number of well-known specialists whose participation might have been anticipated, critical perusal of certain articles they might have written fails to disclose that anything has been lost in calibre thereby.

Vol. 1 is concerned with geology and production—350 pages of the former and 500 of the latter. As with the remainder of the treatise, it is just not possible within the scope of a review to indicate the breadth of the special subjects covered. It is only by comparison with corresponding matter written years ago that the remarkable advances in procedure and ideas can be gauged. They are perhaps most spectacular in the case of the methods available for geological mapping, but are equally true as regards production. The repressuring of fields, the use of gas-lift, the control of oil-field water, and conservation methods generally are all directed towards the elimination of waste and general improvement in the utilization of resources. It is significant of modern dependence upon scientific method that some of the most mathematical articles in the whole compendium are to be found in just those sections which in the past would have been regarded as the exclusive domain of the practical driller.

Since the success of an industry must depend largely on the standard of its products, it is natural, however, that "The Science of Petroleum" should be concerned outstandingly with chemistry and chemical engineering. These aspects are copiously covered in vols. 3, 4 and 5, dealing with composition, testing, refining and utilization. The sections dealing with cracking, hydrogenation and re-forming are all well done, but are likely to be those which will need revising first. It is in this direction of the tearing apart of the hydrocarbon molecules of petroleum and their rebuilding into even more effective commercial combinations that most progress is being made. What was an almost wholly analytical industry is now largely synthetic in character, quite apart from its modern concern with the production of special chemicals.

Every man interested in oil will wish to possess these volumes. That should apply from driller to depot manager and include the worker with synthetic, as well as natural, petroleum. Incidentally, he will greatly admire their appearance on his shelves, and, whilst reading them, the truly wonderful technique of their production. S. J. M. Auld.

Mental Defect

A Clinical and Genetic Study of 1280 Cases of Mental Defect

By Dr. L. S. Penrose. Pp. 159 + xiv. (Medical Research Council. Special Report Series, No. 229). (London: H.M. Stationery Office, 1938) 2*s*. 6*d*. net.

THE eugenic movement has laid great stress on the burden imposed on the community by the existence in the population of about 1 per cent of mental defectives; and extravagant statements have been made both for and against the possibility of reducing the incidence of mental defect by eugenic measures. Thus it has been stated, on one hand, that mental defect could largely be eliminated by the sterilization of defectives, and, on the other, that it could largely be controlled by prenatal hygiene or improved obstetrics.

Dr. Penrose's report will not please the extremists of either school. It is an extraordinarily painstaking record of facts. No fewer than 1280 patients in an institution, and 56,198 of their relatives, were investigated. With such large material it is possible to classify defectives not only by the grade of mental defect, but also in 76 per cent of cases by their clinical type.

7·3 per cent were due to congenital syphilis or to cerebral trauma or inflammation. Perhaps another 3 per cent (including cases of hemiplegia and disseminated sclerosis) might be put down entirely to environmental effects. In the remainder, genetical causes play at least a considerable part in determining the abnormality.

4·9 per cent of cases were due to mongolism, where genetical and environmental factors interact. For while the condition was ten times as common amongst their relatives as amongst those of other patients, the mean age of their mothers was 38·2 years, as compared with 29·4 years for other patients. 1·0 per cent of cases were due to three well-recognized dominant genes causing epiloia, neurofibromatosis, and Huntington's chorea. There is a very strong case for preventing the breeding of persons afflicted with these diseases, whether mentally defective or not. As, however, new cases constantly occur by mutation, and Huntington's chorea may only show up late in life, this would not abolish the diseases in question, though it might reduce their incidence by more than half.

7–10 per cent of all cases were probably due to fairly clear-cut recessive genes. One of the most striking results of Dr. Penrose's investigation is to make it highly probable that congenital cerebral diplegia, which accounts for 5·1 per cent of all cases, is a recessive character. The segregation into normals and abnormals was unusually clear cut, and there was consanguinity in 9 per cent of cases. Other recessives include phenylketonuria, a metabolic abnormality which always causes mental defect; cerebromacular degeneration; retinitis pigmentosa; deaf mutism in some families; and probably cretinism. The frequency of consanguinity in other cases suggests the presence of recessive genes.

But the majority of cases were not so simply determined. There was a good deal of certifiable defect, and still more dullness, among the parents and other relatives. This was particularly so in the case of simpletons (feeble-minded). This is what we should expect if the milder grades of mental defect were determined mainly by the interaction of a number of partly dominant genes, and to a small extent by the environment.

What practical steps are suggested by the report? 7–9 per cent of the defectives had one parent sufficiently defective to be certified or certifiable. It follows that had all defectives of certifiable grade a generation ago been segregated or sterilized, 7–9 per cent of these patients would never have been born. This number must possibly be reduced for the whole population, as defective children of defectives are perhaps more likely to be institutionalized than defective children of normals.

Again, 3·5 per cent of all patients had consanguineous parents. Had first-cousin marriages and the illegal unions of closer relatives been prevented, 2·4 per cent of the defectives would not have been born. Finally, 4·7 per cent of the patients had thyroid disorder, of which an early treatment would in many cases have cleared up the disease; 3·9 per cent had congenital syphilis, which is preventable. Others were victims of birth injury, meningitis, and encephalitis, which are at least partially preventable. The cases of pituitary and other endocrine disorder are likely to be brought within the scope of therapeutics fairly soon, if they are not yet so. Since diabetes can be dealt with by insulin, a hormone controlling the oxidation of phenol-pyruvic acid may yet be found.

It would seem, then, that negative eugenics and therapeutics are about equally hopeful as preventive measures, whilst the prevention of inbreeding, though not negligible, is definitely less promising. But all three measures would not, in the present state of our knowledge, prevent 20 per cent of cases.

We need more knowledge, and this report certainly lays the foundations for future research. I have no doubt that it is the most important contribution to human genetics which has been made for many years in any part of the world, and the Medical Research Council, the Darwin Trust, and the Royal Eastern Counties Institution, are to be unreservedly congratulated on it. The diagnosis and family history of every single case is given in an appendix which will be of the very utmost value. However, certain parts of the report require amplification, which they will doubtless receive elsewhere.

I trust that this report may be the beginning of a series which will be as valuable as those on nutrition and bacteriology, which are, of course, indispensable. J. B. S. HALDANE.

The Gorilla in its Home

In Quest of Gorillas

By Prof. William K. Gregory and Henry C. Raven. Pp. xvi + 241 + 110 plates. (New Bedford, Mass.: The Darwin Press, 1937.) 3.50 dollars.

IN the summer of 1929, a party of four scientific men, led by Henry C. Raven, of the American Museum of Natural History, left New York to visit the homelands of the gorilla in Africa. The doyen of the party was W. K. Gregory, the leading authority in all that relates to the structural history of anthropoids, living and extinct. The two other members were Prof. J. A. McGregor, known at home and abroad for his faithful reconstruction of extinct forms of humanity, and Dr. E. T Engle, anatomist, Columbia University. The expenses of the expedition were paid by that University.

Coming by way of Europe, the expedition visited Brussels and Paris, where, after much cross-examination, permission was obtained to shoot five gorillas "for scientific purposes", two in the mountainous country to the west of Lake Kivu and three in the French Cameroon.

On August 4, 1929, the expedition pitched its camp on the western fringe of the great forest to the west of Lake Kivu and nearly 7,000 feet above sea-level. Their camp occupied a corner of the lands of an experimental farm; nothing can illustrate better than this the rapidity with which equatorial Africa is being transformed. The local gorillas proved to be the most elusive of animals; their tracks were everywhere, their nests or beds—often freshly made—were plentiful; dung, recently dropped, knuckle impressions in the mud, and broken and stripped twigs and branches marked the trail left by a passing group. The rustle of branches or a black arm moving amongst them, a bark or a grunt, a momentary glance of a moving form in the thick undergrowth proclaimed the vicinity of a group, but it took Mr. Raven six weeks of stalking to secure the two specimens of the Kivu gorilla. Prof. McGregor was ever ready with his camera; even after six weeks of patient and skilled waiting, not even a snap—much less a film—had been obtained.

The first gorilla shot by Mr. Raven—a male—weighed 460 lb.; with its litter—the total weight which had to be carried across twelve miles of country cut by ravines and clothed with thick brush—was 600 lb. This fact will give some idea of the toil which men of science are willing to undertake in the pursuit of knowledge.

On September 19 the expedition struck camp in the Kivu mountains and set out for the French Cameroon, which was reached on November 14. Africa was crossed from east to west by motor-car, river steamer and railroad, the route taken being that blazed by Stanley. The expedition pitched its new camp on the western fringe of the great Congo Forest. The western gorilla, which Dr. Gregory regards as the parent form, the eastern or Kivu being but a variety of the western, was just as elusive and as hard to come by in West as in East Africa. Day after day Mr. Raven followed roving bands, often hearing them but rarely obtaining a passing glimpse. When one district had been searched in vain, another was commended as an infallible source of supply. After spending five weeks in the French Cameroon without success, the party broke up. Mr. Raven was left to pursue the quest alone, the other members of the expedition being obliged to return to New York to resume their vocational duties.

The first part of this book is written by Dr. Gregory; he is an instructive and entertaining writer, but the chapters which hold the reader are those wherein Mr. Raven tells what he saw and what he felt while hot on the gorilla trail. Mr. Raven has served a long apprenticeship to jungle life in many parts of the world. He soon realized that if he were to succeed in the quest for gorillas he must live as natives live—and sleep where the gorilla sleeps: which he did, with the usual result—a devastating illness, one which almost cost him his life. He spent more than a year in the French Cameroon and ultimately obtained the three covenanted specimens.

Incidentally, much is to be gleaned from the pages of this book, which throws light on the habits of the gorilla. In the thick jungle, the gorilla has the advantage of man; when he observes hunters' crawling in pursuit, the gorilla must wonder how a being, so ill-adapted as man, ever came into existence. In spite of his enormous strength, the gorilla is a peace lover. He never sets out deliberately on the war-path; all his 'scraps' are accidental, the result of some man, woman or beast intruding into his family circle without giving sufficient warning. But when he has to fight, as when the group he leads is in danger, he shows always the utmost courage, giving his life when necessary. It is this instinctive trait which is the undoing of the male gorilla; he falls a victim when he turns to defend his flock. The natives assert that gorillas talk at night; the most that Mr. Raven could hear were noisy movements in their stomachs and a hissing—apparently an expiratory movement of the lips.

The real danger to which the gorilla and chimpanzee are exposed is not the hunter but the planter, native and European. Gorillas are destructive feeders when they invade gardens and plantations. They are also counted good to eat by most natives of West Africa. The total number of gorillas cannot be large; I doubt if there are 10,000 of them, even when western and eastern are added together. Prof. Gregory thinks they may be increasing their numbers in certain districts.

A. K.

Significance of the History of Science

The History of Science and the New Humanism
By George Sarton. (Colver Lectures in Brown University, Elihu Root Lecture at the Carnegie Institution of Washington.) Pp. xx + 196. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1937.) 8*s*. 6*d*. net.

One welcomes especially any fresh utterance of Dr. Sarton on general lines, because he devotes himself too exclusively to the learned studies of which he is a master and speaks too seldom on the wider aspects and applications of those studies, on which he has so much to tell us. He is at the same time the most eloquent and convincing prophet of the value of the history of science as a discipline and the man best qualified on the history itself. It is a unique position and one envies the United States for possessing him.

In the volume under notice, Dr. Sarton publishes the substance of four comparatively popular lectures which he was invited to give by the Brown University and the Carnegie Institution of Washington. They are all full of inspiration and of good sense. Sarton does not overpress the claim for instruction in the history of science. He would even admit that it is not food for every palate. But he strongly and truly insists on its educational value as a central progressive and co-ordinating study, when taught by those who have an adequate preparation both in the sciences themselves and in general history, and applied by the learners in the same spirit. He makes the sound, though somewhat disquieting, remark that though there is no mental discipline so attractive and easy to receive, there is also none more difficult to impart. It is another case of the dominance of the specialist and the urgent need of more synthetically trained minds.

Of the four chapters, that on the relation of East and West and that entitled "The New Humanism" contain the freshest material and the most interesting detail. Dr. Sarton points out most seasonably that there should be no rivalry between West and East in the building up of science, for the creative movement was reciprocal. The East lit the first torch, which we know from recent discoveries in Babylonia and Egypt to have been a much brighter one than was at one time supposed. Then the Greeks took it up and made the blaze which has since illuminated the world. But before the work of the Greeks had been recovered and extended in the modern world, the light had gone back again to the East and was tended for centuries by the Arabs and Indians until the early Renaissance in Europe.

There are some specially interesting particulars here as to the function of the Jews in this matter. They were for long the linguistic intermediaries between East and West, though, after the middle of the thirteenth century, they lost this position of linguistic and national isolation and tended to become—educationally—one with the nationals of the Western countries where they lived. Thus, when we come to Spinoza, "we do not count him any more as a Jewish philosopher in the sense in which we counted Maimonides or Levi ben Gershon. He is one of the founders of modern philosophy, one of the noblest representatives of the human mind, not Eastern or Western, but the two unified".

Dr. Sarton's remarks on the right programme for a 'humanist' education will also be read with profit. He denounces an artificial international language, thinks that mathematics is the true international medium, but that everyone should have a usable knowledge of at least two of the great world-tongues. Ancient languages must, by the press of new knowledge, be left more and more to the specialist.

Tables Annuelles Internationales de Constantes et Données numériques :

International Annual Tables of Constants and Numerical Data. 9 : Electromotive Forces, by Prof. H. S. Harned ; Oxidation-Reduction Potentials, by G. Åkerlof. Vols. 11–12 (1931–1936), Section 60. Pp. iii+45. 25 francs. 13 : Faraday Effect, by M. Schérer ; Magnetic Birefringence, Electric Birefringence, by Prof. A. Cotton and J. Rabinovitch ; Photoelectricity, by G. A. Boutry. Vols. 11–12 (Years 1931–1936), Sections 38–41. Pp. iii+11+12+7+10. 20 francs. (Paris : Hermann et Cie. ; New York : McGraw-Hill Book Co., Inc., 1937.)

PARTS 9 and 13 of vols. 11–12 of "Tables Annuelles de Constants et Données Numériques" cover the period 1931–36. In Part 9, dealing with electromotive forces, H. S. Harned gives a convenient summary of data on concentration cells without liquid junctions, which will be very useful to workers in this field. Among the items of particular interest are Harned's own work on the thermodynamic dissociation constants of weak electrolytes, that of L. F. Nims on amino-acids, and several examples of ionic equilibria in heavy water. There is also a table of recently determined standard electrode potentials. This section should be used in conjunction with Part 3, in which the activity coefficients, free energies, etc., derived from the measurements, are given. G. Åkerlof gives a summary of oxidation-reduction potentials, including the considerable number of organic systems, some of biological interest, investigated during the period.

Part 13 deals with the Faraday effect (M. Schérer), magnetic and electric birefringence (A. Cotton and J. Rabinovitch) and photoelectricity (G. A. Boutry). The latter, which is probably of the greatest general interest, contains a table of recent determinations of the photo-emission thresholds and work functions of metals. Since the elucidation of the theory of the photo-electric effect by Fowler in 1931, it has been possible to evaluate the true work function corresponding to absolute zero, and a considerable number of such determinations have now been made, which are collected here. Other sections deal with the effects of thin films of alkali metals and of complex films on the photo-emission, and there is also a summary of the characteristics of commercial photo-electric cells.

Communication Engineering

By Prof. W. L. Everitt. Second edition. Pp. x+727. (New York and London : McGraw-Hill Book Co. Inc., 1937.) 30*s*.

AN excuse for yet another text-book on the electrical communication of information, that is, by electric wave-motion in space or along wires, is that it is a little better than its predecessors. This to a large extent is true of the present work, since the author's plan is attractive and the subject developed logically, as may be instanced by the general grouping of the chapters ; these are classification of impedance elements, linear bilateral impedances, unilateral and non-linear impedances, coupling between electrical circuits and free space, and coupling between electrical and mechanical circuits.

The reader must not be put off by these and many other strange literary expressions ; the subject is becoming so complicated that continual grouping of ideas is imperative. Nevertheless there is a number of prominent omissions, particularly as one is not warned of them ; phase compensation, for example, should be included for students to-day, for it is as important as the degenerative amplifier, the properties of which are clearly stated. The most useful network theorems are grouped at the beginning, which does not indicate their relative importance, but apart from this the text can be well recommended. L. E. C. H.

The Analysis of Engineering Structures

By Prof. A. J. S. Pippard and Prof. J. F. Baker. Pp. ix+554. (London : Edward Arnold and Co., 1936.) 30*s*. net.

THE final report of the Steel Structures Research Committee completed investigations of first-class importance that have had great influence on the treatment of steel building frames. Both authors of this book were members of that Committee, and they are to be congratulated on so ably incorporating this recent work in a students' text-book on structural analysis. One chapter gives a valuable summary of the main findings and design methods, but elsewhere, as in the chapter on structural connexions, full use is made of the detail investigations of the Committee.

The book as a whole deals comprehensively with the principles on which structural design is based, and the work is carefully classified, wide in scope and—even apart from the work of the Research Committee—up to date, a fact which is shown by the chapter on mechanical methods of stress analysis, although it suffers somewhat from an undue brevity. The book is a notable addition to English text-books on structural analysis and in several respects marks new standards.

The Truth about Vivisection

By Sir Leonard Rogers. Pp. x+182. (London : J. and A. Churchill, Ltd., 1937.) 5*s*.

THE anti-vivisection campaign is persistent, vigorous and clamorous, has ample funds (estimated at £40,000 a year) with which to promote its objects, and uses a variety of methods to do so. It is the aim of Sir Leonard Rogers in this admirable little book to present the reader with the whole truth of the matter. He discusses the working of the Act of 1876 controlling and limiting experiments upon animals, analyses the reports of the Royal Commissions on Vivisection, and describes the valuable results that have been obtained through experiments upon animals in the curative and preventive treatment of diseases, both human and animal. It is a book that everyone should study who desires to ascertain the truth about vivisection, and will be most useful to those who may have to combat anti-vivisection propaganda. R. T. H.

Pasteurization of Milk

By Prof. G. S. Wilson

TEN, or even five, years ago there was a very real cleavage of opinion among scientific workers in Great Britain on the value of pasteurization. In general, the physiologists and biochemists were afraid of the possible damage caused by heat to the nutrient substances in the milk, and were inclined to minimize the part played by milk in the spread of infective disease. Bacteriologists and public health workers, on the other hand, were becoming increasingly impressed with the danger of drinking raw milk, and, in the absence of any convincing evidence to show that the nutritive value of the milk was seriously damaged by mild heat treatment, they strongly favoured the extended use of pasteurization as a means of diminishing the amount of preventable disease.

To-day this cleavage of opinion is much less apparent—indeed, it would scarcely be an exaggeration to say that it no longer exists. The change has come about, as all similar changes in scientific opinion must do, as the result of increased knowledge. During the past few years, several studies have been made on rats, mice and particularly calves, which have agreed in showing that only a minimal amount of damage is caused to the nutritive value of milk by low-temperature pasteurization. In addition, the occurrence of repeated outbreaks of milk-borne disease, some of them accompanied by a relatively high mortality, has gone a long way to convince unprejudiced observers that tuberculosis is not by any means the only infection spread by milk to human beings. It is now recognized that cleanliness is not enough. The milk must also be safe—safe from the risk of spreading disease—if it is to be recommended more freely to supplement the inadequate or unbalanced dietary of certain sections of our population. In view of this increasing unanimity, it will probably be better to give a brief résumé of the evidence on which our present conclusions are based rather than to set out the pros and cons of pasteurization[1], and thus create the illusion of a difference of opinion that now no longer exists. For reasons of space, discussion will be confined to the nutritional and hygienic aspects of cows' milk pasteurized by the official holding process (145°–150° F. for 30 minutes, followed by cooling to 55° F. or below) and sold under licence. Not until these two aspects are fully understood is it profitable to consider the economic implications of compulsory pasteurization which play so large a part in practice in determining opposition to this measure.

The observations of numerous workers[2,3] agree in showing that pasteurization has the following effects. About 5 per cent of the lactalbumin is coagulated; the coagulation time by rennin is lengthened, but the casein clot formed consists of finer particles and is of a more open texture; there is a diminution in the soluble calcium and phosphate, estimated variously by different workers, but probably of the order of 5 per cent; there may be some loss of iodine through volatilization; there is some destruction, at present unmeasured but apparently small, of vitamin B_1; and there is some diminution in the vitamin C content, depending largely on the amount of previous exposure to light and on the presence of copper in the pasteurizing plant. Information on the effect of pasteurization on vitamin D is still deficient, but considering that vitamin D is even more resistant to heat and oxidation than vitamin A, it is improbable that any deleterious effect occurs. As against these positive changes may be set a number of negative findings. Thus it is found from feeding experiments on rats and calves that the biological value of the proteins is unaltered, that there is no detectable change in the availability of calcium or phosphorus, that there is no loss of vitamin A, and that the total energy value of the milk remains unaltered. Furthermore, recent carefully designed experiments on calves[4,5] in which alternate animals were fed for 8–12 weeks on raw and pasteurized milk from the same source, have failed to show any significant difference in growth between the two groups of animals. In each experiment the average percentage weight increase was slightly higher in the group of animals receiving the pasteurized supply, but the differences were such as might easily have occurred by chance variation alone.

In assessing these results in terms of human nutrition it must be remembered that, though cows' milk may be a perfect food for calves, it is not a perfect food for infants. It differs both qualitatively and quantitatively from human milk, and it is deficient in iron, copper, vitamin C, and often in vitamin D. The differences between raw and pasteurized cows' milk are very much less than those between cows' milk and human milk. Deductions, therefore, from animal experiments to man must be made with great caution. Unfortunately, there is a dearth of direct observations to determine the comparative nutritive value of raw and pasteurized milk for infants and children. The only experiment of any size that is on record[6] yielded results which failed to show any significant differences between the two classes of milk. Pending the publication of further observations of this type, we must conclude on the basis of all the available evidence that the nutritive changes produced by pasteurization appear to be comparatively slight, and are such as can readily be made good by suitable supplements to the dietary.

Turning now to the hygienic aspect of pasteurization, we have at our disposal well-documented evidence to show the danger of drinking ordinary raw milk and the protection afforded by adequate pasteurization against milk-borne disease. It is calculated[7] that in 1931 there were 2,600 deaths in Great Britain from tuberculosis of bovine origin and more than 6,000 fresh cases of the disease. Since then our knowledge of the part played by the bovine tubercle bacillus in causing pulmonary tuberculosis has considerably expanded, and there is no doubt that if this calculation were to be made afresh the figures would have to be increased rather than diminished. Undulant fever is a less important disease, but something like 400 cases yearly appear to arise in Great Britain, mainly from milk-borne infection[1]. Of epidemic diseases records[1] are available of the occurrence in Great Britain during the years 1912–35 of at least 103 milk-borne outbreaks of scarlet fever, septic sore throat, diphtheria, typhoid fever, paratyphoid fever, dysentery and gastro-enteritis affecting over 11,000 persons. These figures take no account of epidemic diarrhœa, in the causation of which milk almost certainly plays a considerable part. Our knowledge of sporadic milk-borne disease, apart from tuberculosis and undulant fever, is very deficient, since milk is rarely suspected as a vehicle of infection unless large numbers of cases occur in a short interval of time over a limited area, but as further information accumulates on this subject, it seems likely that the case against raw milk will have to be weighted still more heavily.

Pasteurization, adequately carried out in properly designed apparatus, and conveniently controlled in practice by the phosphatase test, destroys all pathogenic organisms in milk and renders it safe for human consumption. The laboratory and field evidence for these statements is too extensive to quote in detail. Reference may, however, be made to the now well-known observations of Price[8] in Toronto, which have all the force of an *ad hoc* experiment. Briefly, she found that among 300 tuberculous children bacteriologically examined, 15 per cent were infected with the bovine tubercle bacillus. All of these had come from parts of Ontario where pasteurization of milk was not carried out. In Toronto itself, where pasteurization has been compulsory since 1915, not a single case of bovine infection was found, in spite of the fact that 26 per cent of the incoming pooled supply of raw milk before pasteurization contained living tubercle bacilli. Nearer home we may add the recent experience at the Hannah Dairy Research Institute gained during one of the calf-feeding experiments alluded to above[5]. Of 36 calves fed for twelve weeks on raw milk, no fewer than 24 were found, when slaughtered, to be infected with the tubercle bacillus and to have macroscopic lesions of tuberculosis, whereas of 37 calves fed on milk from the same source after holder pasteurization, not a single one appeared to be infected. Apart from tuberculosis, the value of pasteurization in protecting against epidemic disease is well demonstrated by experience in the United States. Examination of the statistical returns shows that milk-borne disease has been practically eliminated from the large cities, where the great majority of the milk is pasteurized, and is now almost entirely confined to the rural districts and smaller towns, where most of the milk is consumed raw[9]. The effect of pasteurization in bringing to an end milk-borne epidemics that are already under way has been frequently and forcibly illustrated during the course of the past few years in Great Britain, notably in the extensive outbreak of typhoid fever at Bournemouth in 1936[10].

In view of this cumulative evidence it is not surprising that public health workers are asking for the control of milk-borne disease by compulsory pasteurization. From the hygienic point of view, this step is merely the equivalent to the treatment of water by filtration and chlorination. Recent experience has shown what widespread public disapprobation follows neglect to exercise adequate control over our water supply, and there seems no logical reason why the public conscience should not be similarly exercised over the safety of our milk supply.

It has been suggested that the right way to control milk-borne infection is to eradicate disease from our milking herds. While not depreciating for one moment the importance of this aim, it must be pointed out that pathogenic organisms may gain access to milk not only from the cow, but also from the human personnel, from the water supply, and possibly from rodents. Even if eradication of cattle disease within a generation or two were possible, it would still leave unsolved the problem of protecting the milk supply from these other sources of contamination.

Pasteurization, preferably accompanied by automatic bottling, alone affords an immediate, practicable, and effective method of ensuring the final safety of the milk as delivered to the consumer.

So far as the available evidence goes, there is no scientific argument against pasteurization. That the introduction of compulsory pasteurization might have widespread economic repercussions may be true, but it is not the purpose of this article to deal with a problem which comes into the domain of practical politics rather than of science. It is enough to show that, provided minor additions are made to the dietary of infants whose sole source of nourishment is pasteurized cows' milk—additions which are almost equally necessary on a dietary of raw cows' milk—there is no reason to fear that the growth and general development of our population would be in any way prejudiced by the extended use of pasteurized milk, while there is every reason to believe that the introduction of compulsory pasteurization, carried out under proper supervision, would lead to the practical abolition of milk-borne disease.

Root-Pressure as a Factor in the Rise of Sap*

By Dr. Philip R. White, Rockefeller Institute for Medical Research, Princeton

THE history of our observations and theories—one can scarcely say our 'knowledge'—concerning the movement of sap in plants has been a rather tortuous one. Beginning with the 'vital' explanations of Hales[1] and Knight[2], in which the living cells were presumed to be the agents largely responsible for sap movement, our concepts have run the entire gamut to the 'mechanical' explanations of Dixon and Joly[3] and Askenazy[4] in which living cells were presumed to take no part in, or even to hinder, the movement of sap. The Dixon-Askenazy scheme is the one generally considered to-day to furnish the most satisfactory explanation of sap movement, while 'root-pressure', first observed by Hales in 1727, is looked upon as a transitory phenomenon, involving negligible forces (maximum value recorded, about 1·5 atm.), the occurrence of which in uninjured plants was subjected to doubt by Molisch[5], and hence probably unimportant.

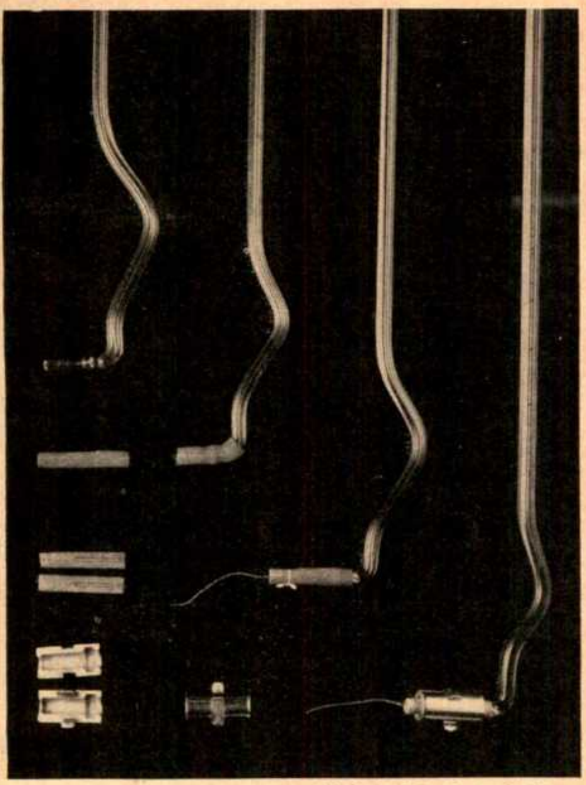
For a number of years, I have been growing excised roots *in vitro*, isolated from all the influences which the rest of the plant normally exert upon the root[6,7]. It has thus been possible to establish with a considerable degree of precision the nature of these influences. It has been shown that the tops of plants provide the roots not only with carbohydrates but also with amino-acids[8] and with materials[9] either identical with or capable of being replaced by at least one vitamin, B_1. On the other hand, roots are not absolutely dependent on the tops for hormones, as was once supposed. Most of these studies have been carried out on roots of tomato which have been maintained in continuous culture for about five years (250 passages). Roots of a number of other plants have also been studied. Those of aster (*Callistephus hortensis* Cass.) have been grown for about 100 passages, those of *Nicotiana langsdorffii* Weinm. for about 75 passages, those of *Brassica nigra* Koch, *Trifolium repens* L., *Petunia violacea* Lindl., *Fagopyrum esculentum* Moench, *Daucus carota* L., and *Helianthus annuus* L. for about 50 passages and those of a dozen more species for lesser periods.

The capacity to grow as autonomous units seems to be a general property of roots, at least among the dicotyledons. Now, one of the striking and universal features of these root cultures is that they retain their morphological characteristics, their growth polarity and their vascular strands. These strands are normally developed, although the cultures are grown floating upon, or immersed in, the liquid nutrient. Since in such cultures no obvious function could be ascribed to such strands, their presence seemed anomalous. If, however, a continuous flow of liquid be assumed to take place through these roots, that is to say, if they continue to function in culture in the manner postulated by Hales, as pumps, then the presence of vascular strands would be understandable. The root cultures seemed to offer a possible means of answering the old question: "Is root-pressure a real function of normal roots, or is it merely a wound reaction? And if root-pressure is real, what is its true magnitude?"

---

* Substance of a paper presented on December 28, 1937, before the Physiological Section of the Botanical Society of America at the annual meeting of the American Association for the Advancement of Science at Indianapolis, under the title "Root-pressure: An Unappreciated Force in Sap Movement".

To answer this question, manometers were developed to receive single growing roots, to collect any liquid which might be secreted from their bases, and to measure the force with which such liquid might be secreted. In its final form, the lower part of the manometer was constructed as shown in the accompanying figure. The upper end was attached to any of a variety of devices for measuring the amount of liquid secreted or the pressure developed.



[*Photograph by J. A. Carlile.*

MANOMETER ASSEMBLY CONSISTING OF SPECIALLY DESIGNED GLASS TUBE, RUBBER HOSE AND METAL CLAMP. BY MEANS OF THIS ASSEMBLY, A SINGLE GROWING ROOT CAN BE ATTACHED TO A RECORDING APPARATUS AND THE FORCE WITH WHICH WATER IS SECRETED FROM ITS BASE CAN BE MEASURED. $\times \frac{3}{8}$.

Qualitative results of tests made with such manometers were presented a year ago[10]. It was shown at that time that a continuous unidirectional flow of liquid does occur through such roots, that over a period of several days the quantities of liquid secreted may represent many times the volume of tissue increase due to growth of the culture in the same period, and that this secretion may take place against considerable pressure. Since then some measurements of the magnitude of the secretion force have been made. Although no absolute value has been obtained for the maximum secretion force, the results appear to warrant discussion at this time.

Simple straight manometers 500 mm. long and filled with either water or mercury gave identical curves, plotting height of column against time. No diminution in secretion rate with increase in column height was observable, even under mercury (maximum pressure 500 mm. mercury = 0·7 atm.). Using a levelling bulb, pressures up to 1,780 mm. mercury (2 atm.) were imposed, again without appreciably retarding secretion. When the manometers were attached to a compressed air tank and pressures up to six atmospheres (90 lb. per sq. in.) were applied, the secretion curves obtained were still indistinguishable from those obtained without imposed pressure. At pressures greater than 90 lb. per sq. in. the apparatus failed. Apparatus is now ready which, it is hoped, will permit the study of secretion under still higher pressures; but no measurements have yet been made with it. It is noteworthy that the roots have at no time failed to secrete continuously against all pressures to which it has been mechanically feasible to subject them. Failures have all been due to the apparatus—not to the roots.

The detailed secretion curves show a striking diurnal rhythm, secretion being practically at a standstill during the night, beginning at about 6 a.m., reaching a maximum rate about noon, and then falling off in quantity, though apparently not in force, during the afternoon. Since the secretion rate was unaffected by pressures up to 6 atm., it is clear that the true secretion pressure must greatly exceed this value. It is my opinion that it must reach at least 10 atm. and is probably much greater than that. This value is for single, isolated, normally metabolizing rootlets of tomato, a plant which rarely attains a height more than a tenth that to which such a force is capable of lifting water. It is thus evident that 'root-pressure' is a very real phenomenon, and is by no means the insignificant factor which text-books have led us to believe. Failure to appreciate it in the past century has probably been due to the necessity, before the development of the root-culture technique, of working with traumatized, moribund and hence abnormally metabolizing materials.

It is not suggested that mechanical factors, such as transpiration pull, cohesion, capillarity, imbibition, etc., do not play a considerable part in sap movement. Under conditions of high transpiration, they probably do account for the movement of large volumes of water through the plant. But under certain conditions such, for example, as those existing during the rainy season in many tropical forests, some or all of these mechanical processes must cease to function. Under such conditions, root-pressure, as demonstrated by these experiments, seems quite adequate to supply water to the tops of even the tallest trees.

No attempt will be made at present to explain how this force may be developed. We are interested, however, in determining if a diurnal rhythm of respiration rate exists corresponding to the observed rhythm of secretion, to extend the quantitative study of the phenomenon to roots of species other than tomato, including roots of some trees, and especially to extend the curve of secretion rate as influenced by imposed pressure far enough so that some estimate of the maximum secretion pressure can be obtained and compared with the osmotic values of the tissues involved. It is hoped thus to throw some light not only on the question of sap movement but also on the mechanism of secretion.

Clay

FOR fifty years or more a number of people have been endeavouring to give a satisfactory answer to the question, "What is clay ?" Instead of a simple answer which meets all requirements, no adequate definition has been found. Geologists define as clay many substances which potters would reject. Chemists look for a definition based on chemical composition and fail to obtain satisfaction because many commercially useful 'clays' differ so greatly in composition that no satisfactory correlation seems possible. The highly plastic blue clay used by glove manufacturers seems to have little in common with the hard grey fireclays of the Coal Measures and even less with the china clays of Devon and Cornwall, or the kaolin of the text-books. Plasticity—which is supposed by many people to be the chief characteristic of all clays—is almost absent from some kaolins the composition of which causes them to be regarded as the purest of all clays and the 'typical clay-substance' of numerous authors and investigators. On the other hand, many substances become plastic when suitably treated, though their compositions are so different from any kind of clay that the inclusion of plasticity as an essential part of any definition has often led to confusion.

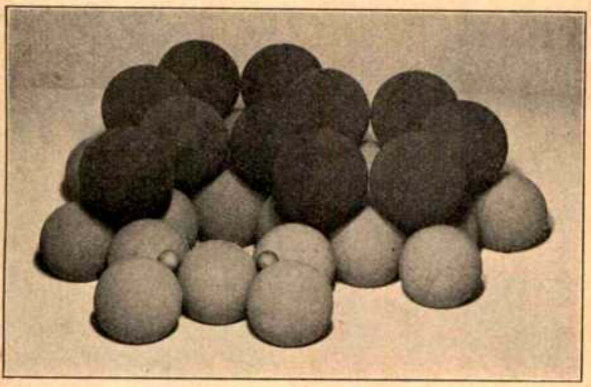
An important step forward was taken when Seger succeeded in separating extremely small particles of almost constant composition from several varieties of clays used in the manufacture of bricks, tiles, and pottery. Further investigations along this line seemed to show, however, that Seger's 'pure clay' or 'clay-substance' does not exist in the sense that 'pure silica' or any other 'pure' chemical compound exists. The variations in composition and properties of the 'purest clays' obtained from various sources differed too greatly for clay to be regarded as a definite chemical compound.

The whole subject remained in this inchoate state until a few years ago, because the 'purest' clay particles obtainable are so small as to be, for the most part, outside the range of the most powerful microscopes. Many seem to be readily converted into the colloidal state, if they do not exist in it when found, and as their precise shapes cannot be ascertained by direct observation they were regarded as amorphous. It seemed, indeed, as though the limits of investigation, as applied to clay particles, were rapidly being approached when a new line of research was opened out by the discovery that X-rays enabled the crystalline form of substances to be recognized even when the particles were of sub-microscopic dimensions. This line, so ably developed by Sir William Bragg and his son W. L. Bragg, has now changed the whole outlook on the constitution of clays and has successfully revealed the principal features of the structure of clays, though many details still await explanation.

The present position was described on November 19 by Sir William Bragg in a Friday evening discourse at the Royal Institution and may be summarized as follows:

Many mineral and other silicates have been found, by X-ray analysis, to consist of sheets or layers of atoms piled one upon the other, much as a series of balls of different sizes may be placed in a pre-arranged heap (see accompanying illustration). In both complex silicates and clays, the atoms (represented as spheres at the apices of tetrahedra) form a pattern of rectangular cells or units, and the various sheets or layers must fit perfectly in combination even if they differ slightly when in separate existence. Such differences are easily overcome when two or more layers are laid on each other or when they grow together. The lengths of the sides of these imaginary rectangles have been measured, and from them the probable structure of various clays deduced.

The structure of the halloysite crystal (which is a characteristic constituent of some fireclays) has been determined by Mehmel, and the dimensions (in angstroms) of the unit (rectangular) cell are $a = 5{\cdot}20$, $b = 8{\cdot}92$, $c = 10{\cdot}25$, and $\beta = 100$. The value of c corresponds to four oxygen or hydroxyl sheets piled on one another. The structure of several typical clays and other minerals is shown in Table 1, each sheet or layer being enclosed in a rectangle of dimensions $a \times b = 5{\cdot}2$ A. $\times$ $8{\cdot}8$ A. The height of the cell depends mainly on the number of sheets and on their thickness.



ARRANGEMENT OF THE ATOMS IN A SHEET OF HYDRATED SILICA. THE O-ATOMS FORM THE LOWEST LAYER; THE OH-GROUPS, SHOWN DARKER, REST ON THEM. THE SILICON ATOMS OCCUPY THE SPACES BETWEEN; TWO SILICON ATOMS HAVE BEEN MADE VISIBLE BY THE REMOVAL OF OVERLYING SPHERES.

It should be noted that when halloysite is slightly heated, its two middle sheets of hydroxyl collapse into one sheet consisting of four oxygens and two hydroxyls. Four oxygens and eight hydrogens are expelled in the form of water, though no water, as such, exists in the clay. This expulsion of 'combined water' has long puzzled chemists, though they were aware that it originated in the decomposition of hydroxyl groups. As shown in Table 1, the slightly heated halloysite (meta-halloysite) has the same structure and composition as kaolinite and, presumably, as kaolin and china clay. Further heating of halloysite and kaolinite appears to result in the formation of free alumina and free silica, and the expulsion of water as steam, but further investigation is necessary to prove this.

Several well-known clays appear to be derived from, or closely related to, montmorillonite, which, as shown in Table 1, consists of two sheets of silicon atoms with a sheet of aluminium atoms and two sheets of oxygens and hydroxyls between. The greater thickness of the montmorillonite cell, as compared with pyrophyllite and mica, is attributed to further intervening sheets of water. The structural analogy of montmorillonite with hydrated silica, brucite, and gibbsite is clearly shown in the table.

TABLE 1.

Hydrated silica	Brucite	Gibbsite	Halloysite	Kaolinite
4 OH 4 Si 6 O	6 OH 6 Mg 6 OH	6 OH 4 Al 6 OH	6 OH 4 Al 6 OH 4 OH 4 Si 6 O	6 OH 4 Al 4 O + 2 OH 4 Si 6 O
	thickness = 4·73	thickness = 4·86	thickness = 10·25	thickness = 7·2

Pyrophyllite	Montmorillonite	Mica (Muscovite)
6 O 4 Si 4 O + 2 OH 4 Al 4 O + 2 OH 4 Si 6 O	6 O 4 Si 4 O + 2 OH 4 Al 4 O + 2 OH 4 Si 6 O water layer or layers	6 O 3 Si + Al 4 O + 2 OH 4 Al 4 O + 2 OH 3 Si + Al 6 O 2 K
thickness = 9·4	thickness = 9·2–21·4	thickness = 10·0

In Sir William Braggs's opinion, the main problem of the constitution of clays has now been solved: there are only two different groups of clays: (*a*) those allied to halloysite, kaolinite, nacrite, and dickite; and (*b*) those allied to pyrophyllite, the latter including montmorillonite, beidellite, bentonite, and fuller's earth, which differ chiefly in their metal contents, for example, in the extent to which gibbsite is replaced by brucite.

The suggested structures explain the colloidal properties of the smallest clay particles, the relatively 'enormous' effect of minute additions of alkalis or acids to clay pastes and suspensions, and they aid greatly in explaining variations in plasticity. Recent measurements by Bradley, Grim and Clark[1] have shown the existence of a well-defined set of hydrates in which the c axis increases regularly with the water molecules introduced into the unit cell. The looseness of these water molecules gives easy movement to the clay particles and yet prevents the complete loss of shape of the mass.

This peculiar ability of absorbing water molecules and arranging them in successive sheets in the layer-like structure of the clay crystal, causing an increase in the *c* axis but not altering the lengths of the *a* and *b* axes, is, according to Sir William Bragg, "the cause of plasticity". The same structural arrangements also explain the remarkable property of 'base exchange' of some derivatives of montmorillonite clays (zeolites).

To sum up, the structures of the chief clay minerals shown in Table 1 enable clear, reasonable and simple explanations of the chief properties of clays to be formulated. Many details remain to be added, because it is difficult to obtain perfectly pure materials and because of the complications due to the numerous substitutions which are usually present. Now that the general structure of clays has been so clearly elucidated, it should not be difficult to fit the details into their proper places.

All who are interested in the molecular structure of clay, whether theoretically or in connexion with the manifold uses of this very important material, should be very grateful to Sir William Bragg for his masterly solution of a problem which has, for so long, baffled many men of science.

A. B. Searle.

Obituary Notices

Sir R. F. Johnston, K.C.M.G., C.B.E.

We regret to record the death of Sir Reginald Fleming Johnston, formerly commissioner for Wei-hai-wei and a distinguished Chinese scholar, which took place in Edinburgh on March 6 at the age of sixty-four years.

Johnston, who was educated at the University of Edinburgh and Magdalen College, Oxford, where he obtained a second class in the Final Honour School of Modern History, entered the Civil Service of the Hong-Kong Government in 1898 as a cadet. After serving as private secretary to the Governor and acting clerk to the Council and Assistant Colonial Secretary, he was appointed in 1904 secretary to the Government of Wei-hai-wei, then held under lease by the British Government. He remained there until 1919, when his special and profound knowledge of China and the Chinese led to his appointment as tutor to the Manchu Emperor P'u Yi, now the ruler of Manchukuo. This appointment came to an end with the flight of the Emperor in 1924. In 1926, Johnston was appointed secretary to the British Indemnity Delegation, and in the following year returned to Wei-hai-wei as Commissioner, his appointment coming to an end with the transfer of the territory to the Chinese Government. On his retirement, when he was already a C.B.E. and C.M.G., he was promoted to K.C.M.G.

On his return to England, Johnston accepted the chair of Chinese at the School of Oriental Studies in the University of London, an appointment which he held from 1931 until 1937.

As a Chinese scholar, Johnston's knowledge of the language and the people, of their ways of thought and their beliefs, was exceptionally wide, deep and sympathetic, although in this last respect it was distinctly perceptible that his understanding grew and mellowed as time went on. When he left Hong-Kong for Wei-hai-wei, he had already acquired no little insight into the widely varied conditions of life and the character of the peoples of the Far East. He made two extensive journeys of which the first in 1902 traversed Tonking, Yunnan, the Chinese Shan States, the States of the Upper Laos and the plain of eastern Siam, ending at Bangkok. A later and more ambitious journey occupied nearly a year, during which Johnston lived for the most part in close touch with native life. This journey was described in "From Peking to Mandalay". On his transfer to Wei-hai-wei Johnston found himself in the Province of Shantung in close touch with the springs of all that is most traditional and changeless in the life of the Chinese peasantry. His studies here bore fruit in his scholarly and informative "Lion and Dragon in Northern China" (1910). This was followed in 1913 by his "Buddhist China", a sympathetic study of Chinese religious belief and philosophic thought, while his "Letters to a Missionary" (1918) affords a contrast in its trenchantly critical tone. "Twilight in the Forbidden City" (1934) records his experiences as tutor of the Emperor, whom he visited in Manchukuo in 1935, before proceeding to Mukden for the purpose of studying the archives of the Manchu.

Major F. G. Jackson

Major Frederick George Jackson, the Arctic explorer who died on March 13, was born in 1860 and educated at Denstone College and the University of Edinburgh. Attracted by an open-air life, he spent some time on a Queensland cattle ranch before the Arctic regions attracted his attention. A few months on a whaler in the Greenland Sea whetted his appetite and he offered his services to Nansen for the voyage of the *Fram*. But the *Fram's* complement was full and so Jackson decided to organize his own expedition. His plan was to attempt to reach the Pole by sledging north from Franz Josef Land, beyond which he, among others, believed that there existed a land which Payer, in 1873, had called Petermann Land.

In order to test equipment and to gain experience, Jackson decided first to undertake a winter journey in Arctic Russia. He began with a journey through the little-known Waigatz Island and then, failing to achieve his plan of exploring Novaya Zemlya, he set off from Khabarova with a Russian, a few Samoyedes and reindeer sledges over the frozen tundra via the Pechora River to Archangel. From there he went on round the White Sea and across the Kola peninsula to Kirkenes in Norway. His book, "The Great Frozen Land" (1895), is full of notes on natural history and on Samoyedes' customs and folklore. With the backing of Mr. A. C. Harmsworth (later Lord Northcliffe), Jackson left for Franz Josef Land in 1894 and made his base at Cape Flora. The Franz Josef Archipelago was little known beyond the few discoveries of Payer and Leigh Smith. Jackson remained three years in the north, surveying some of the little-known islands and distinguishing himself as a hunter of polar bears, of which he shot about a hundred. Among his companions were W. S. Bruce and A. B. Armitage, who in later years distinguished themselves in South Polar work. The expedition's chief claim to fame was due to the chance meeting of Jackson with Nansen and Johansen. On their return from their long poleward march they had wintered on the north of the archipelago, and in 1895 were on their way west toward Spitsbergen when near Cape Flora they met Jackson, a few weeks before the *Windward* was due. Thus they reached Norway in safety.

After serving in the South African War of 1899–1902, Jackson contemplated a South Polar expedition but his plans came to nothing. He served in the Great War, and in 1919 had charge of Russian prisoners-of-war camps in Germany. Then in 1925 he turned to Central Africa for adventure and big game shooting, crossing Africa from east to west, visiting the Ruanda country and descending the Congo to the sea. Later he investigated the slave trade of Liberia. In addition to his book on Lapland Jackson wrote "A Thousand Days in the Arctic" (1899) and "The Lure of Unknown Lands" (1935). He was a gold medallist of the Royal Geographical Society, a medallist of the Royal Humane Society and a knight of the Order of St. Olaf.

Jackson's work was essentially of a pioneer order, and it was the opportunity to overcome physical difficulty and danger which drew him to the Arctic and later to Africa. Scientific exploration attracted him less than hunting, but he showed much interest in natural history and, where scope was afforded, in native races and their ways. R. N. R. B.

Prof. Anton Lampa

THE academic career of Prof. Anton Lampa, who died in Vienna on January 28 at the age of seventy years, was under the shadow of the political changes occurring in Austria during his lifetime. Educated in Vienna, he studied physics under von Lang and became *Privatdozent* and assistant professor in the University of Vienna. In 1909 he was called upon to fill the chair of experimental physics at the German University in Prague; when, in 1918, Czechoslovakia became an independent State, the German University in Prague came under the authority of the new Government instead of the Ministry of Education in Vienna. Although this did not cause any appreciable change of its activities, and almost all of the professors continued their work, Lampa decided to return to Vienna. Since there was no chair available for him there he again became *Privatdozent* of physics.

This resignation was no doubt facilitated by the variety of Lampa's interests. In experimental physics his name is connected especially with the production of very short electric waves; for several years he held the 'record' with a wave-length of 4 mm. He was much interested in questions of the philosophical foundations of science; here he was a devoted follower of Ernst Mach, and a short biographical sketch which he dedicated to Mach's memory is one of the best introductions into the latter's philosophy. The fact that, already in 1883, Mach, on general principles, had postulated the relativity of every type of motion (including rotation!) enabled Lampa to be one of the earliest to realize the whole significance of Einstein's theory of relativity. It was largely due to Lampa that the German University of Prague was the first to offer to Einstein a full professorship; he held there the chair of theoretical physics from 1911 until 1912, being in close touch with Lampa.

After his return to Vienna, Lampa devoted much time to educational questions. The various societies for the propagation of knowledge could always count on his support, and for a while he was president of one of them. His memory will be held in honour not only by his professional colleagues but also by many others who shared his literary or philosophical tastes and were aware of the sincerity of this very quiet and unostentatious man. F. A. P.

Mr. A. E. Munby

BY the death of Alan E. Munby on January 19, a great personality has been lost to the world of science and art. Mr. Munby's association with the cause for the advancement and development of science teaching for its intrinsic educational value is well known to many. He was for more than thirty years a member (twice chairman) of the Science Standing Committee of the Royal Institute of British Architects, and no effort did he spare in this capacity in obtaining from scientific and educational bodies all over Great Britain, their views, criticisms, and comments on scientific matters and the manner of their propagation. It is to be regretted that he has not lived to see the full benefits of his labours in this respect.

Mr. Munby was educated at Repton. His early training at Durham, where he was assistant to Prof. Bedson and lectured on chemistry in the adjoining counties, his engagement in research at Cambridge (under Sir Arthur Shipley), and at Heidelberg, and in science teaching at Durham, and Felsted School, well fitted him for that sphere of the profession of architect (which he took up at the age of thirty years) for which he is better known. There is no doubt that while a science master at Felsted opportunities occurred to him for considering the practical aspect of the planning of science laboratories which led eventually to an interest in architecture.

It is natural therefore that Mr. Munby's principal works as an architect should lean towards science. Many public schools have had the benefit of his experience. He was responsible for the new science buildings at Clifton College, Highgate School, Beaumont College, University College of North Wales at Bangor, Gresham's School, Hereford Cathedral School, Shrewsbury School, Dover College, and for redesigning the science departments at Uppingham and Cheltenham, and at the Chelsea Polytechnic. He acted also as consultant for the Institute of Tropical Medicine in Shanghai, and for the recently erected science department at Malvern College.

Mr. Munby's publications include: "Notes on Polarised Light" (1894), "Introduction to the Chemistry and Physics of Building Materials" (1909), "Laboratories, their Planning and Fittings" (1921), and "School Laboratory Fittings" (1929).

J. R. S.

Mr. M. W. Hilton-Simpson

WE regret to record the death of Melville W. Hilton-Simpson, anthropologist and African traveller, which took place on March 17 at the age of fifty-seven years.

Hilton-Simpson was the son of the Rev. William Hilton, who added Simpson to his surname in 1888; he was educated at Wellington and Exeter College, Oxford, where he obtained the degree of B.Sc. and the diploma in anthropology. On leaving Oxford, he specialized in the study of African ethnology in the field, making his first journey in North Africa and the Sahara in 1903. His next expedition was to West Africa with Émil Torday as leader, and Norman Hardy, the artist. This ethnological expedition, of the first importance as it proved to be, was carried out on behalf of the British Museum. It covered much unmapped territory in the Kasai basin of the Congo, and brought back valuable anthropological information relating to the tribes of the area, especially the Bushongo, a rich collection of ethnographical specimens, more especially examples of the art of the Congo peoples, and a gallery of paintings by Norman Hardy, which were as remarkable for their accuracy in representing the physical characters of the people, their dress and ornament, as they were for their high artistic merit.

Hilton-Simpson's interests, however, centred not so much in tropical Africa as in the ethnological problems of the northern area of the continent, and more especially in the Berber peoples. For a number of years, each season found him travelling in North Africa, while from 1912 onward he specialized still further in the study of the Algerian Berbers. Seven winters in succession were spent in travelling in the Aurès mountains, where the sporting tastes of himself and his wife established friendly relations with a sporting people and won them exceptional facilities for their investigations. Mrs. Hilton-Simpson's skill as a hockey player not only secured her a place of pre-eminence in the Shawia women's national game, but also gave her their intimate confidence, to the lasting gain of ethnological science.

The work of these years of travel was recorded in "Among the Hill-Folk of Algeria" and "Arab Medicine and Surgery", and in papers in the *Geographical Journal*, the publications of the Royal Anthropological Institute and elsewhere. An especially important contribution to the study of these peoples was a series of cinematograph films of Berber life and industry, taken by Mr. J. Haessler, an American anthropologist, who accompanied them on certain of their expeditions. Apart from his general account of these peoples, Hilton-Simpson's most valuable contribution to the study of their culture was his investigation of their practice of trephining. He made a collection of the instruments used for this purpose, and showed that, like a number of other elements in their culture, the practice was to be traced back to Roman times.

Hilton-Simpson, who served on the Western Front in the Great War and held the rank of captain, was a Chevalier of the Légion d'Honneur and was awarded the Rivers Medal of the Royal Anthropological Institute for anthropological work in the field in 1932.

Lady Gomme

BY the death of Lady Gomme, which took place on January 5 at the age of eighty-five years, folklore studies in Great Britain have lost a staunch supporter of long standing. With her husband, the late Sir George Laurence Gomme, whom she, as Alice Bertha Merck, married in 1875, she took a prominent part in the early activities of the newly constituted Folk-Lore Society, of which they were among the founders. Throughout their married life, and after her husband's death, her organizing ability, her knowledge of her subject and its personnel, and her keen critical faculty, gave her, as of right, a foremost place in every movement for promoting the recording and scientific study of folk beliefs, customs and institutions. Lady Gomme helped to found the two societies, now merged, devoted to the study of folk-dance and song, and strongly influenced the late Sir Cecil Sharp in his work of collecting folk-songs and dances. She herself was the author of two works, which have long been regarded as standard books of reference and models of their kind—"Children's Singing Games, with the Tunes to which they are Sung" (1894, Second Series, 1895) and "A Dictionary of British Folk-Lore, Vol. 1: Traditional Games of England, Scotland and Ireland" (Pt. 1, 1894; Pt. 2, 1898).

WE regret to announce the following deaths:

Mr. F. G. L. Bertram, deputy director of civil aviation from 1926 until 1935, on March 24, aged sixty-two years.

Capt. T. S. Taylor, founder and a director of Taylor, Taylor and Hobson, Ltd., manufacturing opticians, on March 14, aged seventy-four years.

News and Views

Solar Radiation as a Cause of Ice Ages

The supplement to this week's issue of Nature (p. 591) consists of Sir George Simpson's discourse at the Royal Institution on "Ice Ages". The striking advances of great ice sheets over large areas of the globe which have occurred at long geological intervals have attracted a great deal of attention from geologists, who have described their extent, oscillations and associated phenomena in a huge volume of literature, and there has been much speculation, some of it very wild and baseless, as to their causes, but they have been little discussed from the point of view of physical meteorology. With so much ground to cover in a short time, Sir George Simpson presented the geological results in broad outline, ignored the speculations, and concentrated on the theory of variations of solar radiation as a cause of ice ages which is his own especial contribution to the subject, built up by a number of important researches during the past few years. It has previously been assumed that widespread glaciation required a general fall of temperature, one cause of which might have been a *decrease* of solar radiation; Sir George demonstrated on physical grounds that glaciation is more likely to result from an *increase* of solar radiation. This would have little effect on temperature, but would cause increased snowfall in high latitudes and at the same time heavy rainfall ('pluvial periods') in lower latitudes. That such a paradoxical state of affairs is actually possible was shown by a simple and beautiful experiment in ice formation performed at the discourse and illustrated in the text.

Further Evidence relating to Peking Man

In another column of this issue of Nature (see p. 614) Prof. Franz Weidenreich describes further discoveries relating to Peking man—fragments of femora and part of a humerus. These were extracted from material excavated in the cave of Choukoutein in July last, shortly before further investigation was abandoned on the approach of hostilities. For the actual discovery science is once more indebted to the care and skill as an investigator of Mr. W. C. Pei, by whom the first *Sinanthropus* skull was discovered in the Choukoutien cave in 1929. In view of the fact that little skeletal material of *Sinanthropus* has been discovered in the cave, apart from skulls and teeth, the latter now numbering well over a hundred specimens, the new material is of no little importance, as Prof. Weidenreich shows, both in the light it throws on the build and carriage of this early member of the human family, and also for purposes of comparison with other forms. Thus, for example, Prof. Weidenreich deduces from the larger of the two femoral fragments, which he argues to be feminine, that as reconstructed, it points to the stature of its former owner having been approximately five feet, indicating a stature in the male of five feet four inches. Further, the characters of the leg bones and the humerus agree in indicating that, while the femur presents certain primitive characters, which are enumerated, distinguishing it from that of recent man, nevertheless Peking man walked upright. It is possible that in this respect *Sinanthropus* had the advantage over Neanderthal man. The upper limbs had been completely relieved from the function of locomotion. This freedom of the upper limb would accord with the relatively advanced character of the stone industry which has been discovered in the cave. In other respects the new evidence throws further light on the culture of Peking man. The scorching of one of the bones corroborates previous evidence that *Sinanthropus* had attained the use of fire, while the way in which the bones have been broken—the illustration suggests that they have been hacked off by a stone implement—points in the same direction as the evidence of the skulls—to cannibalism.

Dr. Adolf Mahr

The Court of the University of Edinburgh at a meeting held on March 22, appointed Dr. Adolf Mahr to be the Robert Munro lecturer in anthropology and prehistoric archæology for 1938–39. This lectureship was founded in memory of Dr. Robert Munro, most distinguished and widely-known of Scottish archæologists, whose work on palæolithic man and on the lake dwellings of Europe placed him in the front rank of the students of prehistory of the late nineteenth and early twentieth centuries. The choice of Dr. Mahr as Munro lecturer at the present juncture is peculiarly appropriate. Born and educated in Vienna, after holding an appointment on the staff of the Imperial (now State) National Museum of Vienna, when he specialized in studies of the Hallstatt period of the Iron Age, Dr. Mahr in 1934 was appointed director of the National Museum of Ireland and keeper of Irish antiquities. In virtue of his office, the responsibility has devolved upon him of adapting to the service of field archæology the State measures of the Irish Government for the relief of unemployment and economic depression. A large number of men have been absorbed in the work of excavating on occupation sites of all periods of Irish history from prehistoric to late historic throughout the country. A measure of these activities in archæological research, which have been pursued under the direction of Dr. Mahr and supervised by him and his assistants, is afforded by the summary of results which formed the substance of the address delivered by Dr. Mahr as president of the Prehistoric Society in 1937, and occupies no less than 175 pages in quarto of that Society's recently published *Proceedings* for 1937 (3, 2).

Royal Geographical Society: Medals and Awards

H.M. THE KING has approved the award of the Royal Medals as follows: Founder's Medal to Mr. John Rymill, for his organization and leadership of the British Graham Land Expedition 1934–37; Patron's Medal to Mr. Eric Shipton, for his explorations around Nanda Devi and Mount Everest and his conduct of the Shaksgam Expedition of 1937. The Council has made the following awards: Victoria Medal to Mr. A. R. Hinks, for his contributions to the study of geodesy and the figure of the earth, map projections, and photogrammetric survey; Murchison Grant to Mr. Martin Lindsay, for his journey across Greenland in 1934; Back Grant to Mr. Thomas Hay, for his contributions to the physical geography of the Lake District; Cuthbert Peek Grant to Mr. Bradford Washburn, for his explorations and glacier studies in Alaska; Gill Memorial to Mr. Ivan Champion, for his explorations and surveys in Papua.

The British Association and Australia

THE Australian Government has decided not to proceed further at present with the proposal to invite the British Association to meet again in the Commonwealth. As it is desired, however, that leading men of science should from time to time be afforded opportunity to visit Australia, it has been decided to issue invitations to a party of six to attend the jubilee meeting of the Australian and New Zealand Association for the Advancement of Science at Canberra in January 1939. It is hoped that the precedent so set will become regular practice at each succeeding biennial meeting of the Association. A grant of £A1,500 towards the expenses of the guests in 1939 has been promised by the Government.

Man and Animals in Great Britain

A MEETING arranged by the University of London Animal Welfare Society (ULAWS) was held in the Beveridge Hall of the University of London on March 22 to discuss "Man's Relation to Nature and his Response" with reference to "the Survey and Regulation of British Fauna". The chairman, Sir P. Chalmers Mitchell, said that the so-called 'balance of Nature' is a myth and has not existed since glacial times, when there were no animals in Britain to be balanced. We interfere too much for there to be one and interference is no good without knowledge. The Marquess of Tavistock showed how conflicting interests make legislation difficult. Fruit farmers and the owners of grouse moors oppose the protection of bullfinches and peregrine falcons respectively. There is no need to fear the introduction of wild birds for, unlike alien rodents, they find competition too strong. As regards method of control, there is no difficulty in shooting deer in the Highlands, but in the wooded Lowlands hunting is kinder. Shooting is often unkind to foxes owing to the uncertainty of aim. Otters are neutral in sporting streams, killing some game fish but keeping down eels; but they are harmful in trout hatcheries and to ornamental wild fowl. Protecting stoats and weasels to keep rabbits down is a fallacy. Prof. F. A. E. Crew referred to the need for research on the ecology of British mammals; he suggested that we should have something like the U.S. Biological Survey, that the Bureau of Animal Population should be supported, and the staffs of museums and university departments should be enlarged. Sir Roy Robinson, chairman of the Forestry Commission, said that complaints about his treatment of animals were sentimental and not based on knowledge. Rabbits should be exterminated. There are too many deer and foxes. The only mammal in need of protection is the pine marten, and he would like to harbour them. All birds, except black-game and caper-cailzie, should be encouraged in forests. Other speakers referred to the desirability and the difficulties of rabbit extermination in various parts of Great Britain.

Roman Fortifications in Yorkshire

RECENT evidence of the varied methods of construction adopted by the builders of Hadrian's Wall (see NATURE, March 19, p. 505) lent additional interest to the account of the defensive system of Roman Aldborough, near Boroughbridge, Yorkshire, which was presented to the Society of Antiquaries on March 24 by Mr. J. N. L. Myres and Miss Mary Kitson Clarke. This site, known to the Romans as Isurium Brigantium, was the capital city of the British tribe of the Brigantes, an important people, whose territory covered nearly the whole of the northern part of what is now England south of the Border. The excavation was carried out by Mr. Myres and Miss Clarke for the Roman Antiquities Committee of the Yorkshire Archæological Society. In the course of the excavation, it was found that the north-west wall did not run as shown in the Ordnance Survey map, but that its angle lay farther to the north-west. The main scheme of the defences, it was found, consisted of the wall itself, backed by a bank of clay and sand. This, however, was not constructed until the second century A.D. Previously there appears to have been no system of defence, and Roman occupation had been haphazard. Later, perhaps in the early part of the fourth century, a large bastion had been added to the angle, and at least one small bastion built on to the west wall, not far from the angle. Still preserved to a height of nine feet in parts is the lower story of an internal angle tower, which was a striking feature of the wall in its original form. This had supported some structure rising above the wall. Pottery indicates that a lean-to hut at the back of the tower was occupied in the third century. The excavations will be carried further in the coming season.

Clifton College Scientific Society

THE Clifton College Scientific Society held a conversazione in the Science School on Thursday, March 17. About 350 guests were present, as well as approximately the same number of members of the Society, but the spacious laboratories were not more than pleasantly full. Among the exhibits and experiments, arranged by the boys themselves, were a cathode ray oscillograph, a model geyser, fluorescence in ultra-violet light, a model of a hydraulic ram, the preparation of artificial silk, Bristol's share in the development of chemistry, chemiluminescence, flames and explosions, the effect of plant hormones, living elvers from the Severn, and experiments upon animal respiration. Lectures upon colour and upon liquid oxygen, with demonstrations, were given by two members of the Society, and a third entertained visitors by chemical conjuring performed to the accompaniment of an almost professional patter. The aeronautical section—a comparatively new but already vigorous branch of the Society—staged a topical exhibit of aeroplane parts, including a collection of bombs, while in the Science Library were displayed many scientific classics and autographs of famous men of science. Some of the original quartz glass, made by W. A. Shenstone while at Clifton, was on exhibit in one of the corridors, where a collection of the elements, arranged by a former member of the Society when still at school, also attracted much attention. One of the most popular features of the evening was a *tableau vivant* of Lavoisier and his wife, after the well-known picture by David. Among the guests were Sir John Inskip, Profs. M. W. Travers, W. E. Garner, C. M. Yonge, R. J. Brocklehurst, A. Rendle Short and A. M. Tyndall, Air Commodore Dalzell-McKean, and the head masters and science masters of many neighbouring schools.

Acquisitions at the British Museum (Natural History)

THE British Museum (Natural History) has received as a donation from Lord Sudeley the skins of three *Colobus* monkeys from Mount Kenya, *Colobus polykomos kikuyuensis*. One of the specimens is of exceptional interest, being nearly a full albino, the only black hairs remaining being a few scattered hairs on the back and a small V-shaped marking on the crown of the head. These specimens came from close to Nanyuki, situated on the equator on the western slopes of Mt. Kenya at an elevation of about 8,000–9,000 ft. These white or semi-white Colobus monkeys apparently belong to one family group, as they are all found in one very restricted locality on Mt. Kenya. Lord Sudeley shot the specimens himself and reports that the eyes were of normal colour and not the eyes of an albino. Lord Moyne has presented to the Museum the zoological collections made by M. J. Delacour and Mr. J. S. Colman during the recent cruise of his yacht *Rosaura*. These include material from the coast of Greenland, southwards to the West Indies, Brazil and the coast of West Africa. The collection when worked out will probably prove of prime importance for several distinct branches of zoological inquiry. The Royal Society has presented a set of specimens of the volcanic rocks of Montserrat in the West Indies, collected by Mr. A. G. MacGregor, who was a member of the Royal Society Expedition which visited the island in 1936 to investigate the causes of the recent earthquake activity and its relation to the vulcanology. A piece of meteoric iron, found last year at Kumerina in Western Australia, has been presented by the Public Library, Museum and Art Gallery at Perth. A polished specimen of 'Brazilian onyz', an ophicalcite worked in the Argentine, has been presented by Messrs. John Bolding and Sons, and the Cookson Lead and Antimony Company has presented a remarkably fine specimen of metallic antimony crystals.

Rubber Technology Conference

A RUBBER TECHNOLOGY CONFERENCE, under the auspices of the Institution of the Rubber Industry, has been arranged to take place in London on May 23–25, under the honorary presidency of Sir William Bragg. The Conference is being supported by the leading organizations connected with the rubber producing and manufacturing industries and by many other scientific and technical societies; altogether, some seventy organizations in Great Britain, Canada, South Africa, British Malaya, Ceylon, the United States, Austria, Belgium, France, Germany, Holland, Italy and Poland will be sending official delegates to the Conference. These include the Research Association of British Rubber Manufacturers and many of the other industrial research associations operating under the Department of Scientific and Industrial Research. More than seventy papers have already been promised from authors representing most of the countries just mentioned. This excellent response promises to make the Conference an outstanding event, at which a notable gathering of rubber technologists and scientific men interested in rubber from at home and over-seas is expected. A special feature of the Conference will be a symposium on methods of improving and evaluating the durability of rubber, but all other aspects of rubber science and technology will be covered by the remaining sessions. An attractive programme of social events, visits, etc., is being arranged. Those desiring to become members of the Conference or to contribute papers can obtain full particulars from the Secretary, Institution of the Rubber Industry, 12 Whitehall, London, S.W.1.

Oil in Osage County, Oklahoma, U.S.A.

A FIELD party of the United States Geological Survey has recently investigated sub-surface geology of the Osage Indian Reservation of Oklahoma, and it appears that there are many localities in this Reservation worthy of exploration from the point of view of oil production. Prior to the issue of the Geological Survey's report, a paper had been written by N. W. Bass, W. R. Dillard, and J. H. Hengst (U.S. Department of the Interior. *Bull.* 886, A) describing several of these localities. In the east-central part of the Reservation, it is believed there may be an oil pool of considerable extent in the Bartesville Sand. Three productive wells have already been drilled. One drilled thirteen years ago had produced 63,000 barrels of oil by the end of

Ice Ages*

By Sir George Simpson, K.C.B., F.R.S.

IT is now common knowledge that there have been great changes in climate during past ages. The geological evidence is perfectly clear that luxuriant vegetation once grew in Greenland and Spitsbergen, where now the hardiest forms of vegetable life can barely exist on the small areas free from permanent ice. At the other extreme, there is no doubt whatever that at one period a great ice sheet covered the plains of Central India and discharged icebergs into a sea covering what is now the Punjab and North-West India—one of the hottest parts of the earth.

From the geological record it would appear that the climatic changes of the past were in all directions, some warmer and some colder, some wetter and some drier than at present; and some individual localities appear to have experienced all possible climates at one time or another.

It is the problem of meteorologists to study the extent and sequence of the climatic variations in all parts of the world and to seek the cause and mechanism of the changes. Very little progress has been made in that direction up to the present for two main reasons. In the first place, the geological evidence is very fragmentary and often doubtful; and secondly, we know very little of what causes climatic variations and how they are controlled.

The geological evidence of change of climate is based on the fossil relics of past vegetable and animal life and on the physical effects which climatic conditions have on the surface rocks. The former is very difficult to interpret. Heavy vegetation does not always mean warm damp conditions, and both plants and animals may, in the course of ages, change their habits so that the early representative of a species which is now warmth-loving may have been developed in cold surroundings. For this reason, one cannot be certain of climatic conditions deduced from the remains of vegetable and animal life.

The case is quite different when we base our climatic deductions on the physical features of old land surfaces. There can be no doubt when we find traces of salts left when an enclosed sea has dried up that we are dealing with a dry climate in which the rainfall was less than the evaporation. But of all evidences of climate those of ice are the most unmistakable. At the same time one has to be careful, for to-day the presence of ice does not always mean a cold climate. In mountain regions glaciers descend the valleys into climates which are far from arctic, and in New Zealand especially ice action is taking place in valleys which bear an almost subtropical vegetation. There have been periods in the past when ice formation was much more active than at present and of such an extent that only a radical change in climate can have been responsible.

The evidence of the presence of ice during these periods in places where ice is quite impossible with the present climate is so clear that these Ice Ages, as they are called, are the most appropriate subjects for the study of climatic change. If we can find a cause for an Ice Age we shall have made a long step forward towards explaining all changes of climate.

---

* Friday Evening Discourse delivered at the Royal Institution on December 10, 1937.

PRE-CAMBRIAN ICE AGE

In the early days of geology, when evidence of tropical vegetation was found in regions which are now far from the tropics, it was supposed that the high temperature required by these plants was due to the earth still remaining hot from its earlier molten state. The discovery, however, of clear evidence of ice in Pre-Cambrian times, that is, at a time far anterior to the appearance of vegetation, shows that the earth had by then already cooled to its present temperatures. Evidence of Pre-Cambrian ice has been found in North America, Europe, China, South Africa, India and Australia. Some geologists have concluded from this widespread evidence of ice that the Pre-Cambrian Ice Age was extremely severe. So little is known, however, about this early age, and there is no evidence that all these places were glaciated at the same time, that it is useless to try to reconstruct the climatic conditions which then existed. The only certain conclusion is that already stated, namely, that the temperature of the earth was then already sufficiently low to allow of ice formation.

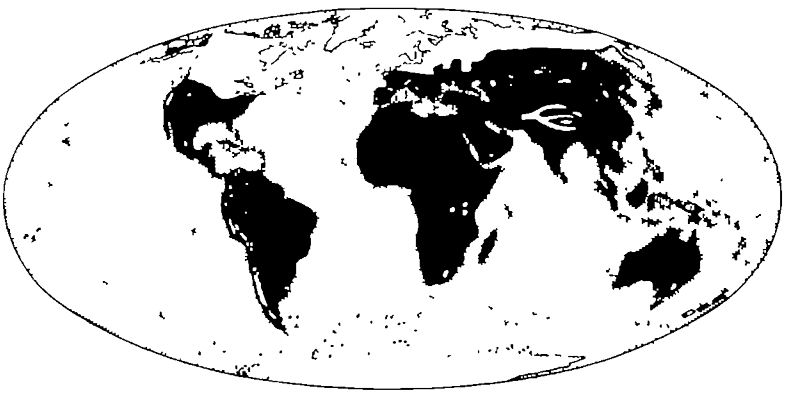

Fig. 1.
PLEISTOCENE GLACIATION: ICE ON LAND SHOWN WHITE, ICE ON SEA SHOWN BY LIGHT STIPPLE.

PERMO-CARBONIFEROUS ICE AGE

After the Pre-Cambrian Ice Age, there is little or no evidence of extensive ice until towards the end of the Carboniferous Period or the beginning of the Permian Period, when evidence of extensive ice appears. This period is called the Permo-Carboniferous Ice Age. The chief regions where the ice was extensive and the evidence undoubted are in South America, South Africa, Australia and India. The latter is well within the tropics, and the evidence is perfectly clear that an extensive ice sheet existed at sea-level in the Central Provinces, India. It is of great importance to notice that, so far as the evidence goes, the ice at this time was all situated within 40° of latitude of the equator, and mainly in the southern hemisphere. Most geologists consider that at the same time the north polar regions had much higher temperatures than at present, luxuriant vegetation growing at this time in both Greenland and Spitsbergen.

This would mean that while there was glaciation within the tropics leading to vast ice sheets at sea-level, there was an almost subtropical climate in polar regions. This is a reversal of the climatic belts which no meteorologist can accept. Owing to the shape of the earth, the equatorial belt must always be warmer than the polar regions. The only explanation the meteorologist can give—and it was given by Wegener—is that the continents were not then in the same position relative to the pole as they now occupy. In other words, the continents have moved since Permo-Carboniferous times.

THE PLEISTOCENE ICE AGE

After the Permian Period, there was another long stretch of time without any marked evidence of ice. This interval includes the whole of the Secondary and Tertiary divisions of geological time.

Evidence of ice was not entirely absent during this period, but geologists are of the opinion that the climate of the world as a whole was warmer than at present. In any event there was nothing equivalent to the extensive ice fields which left their traces in the Pre-Cambrian and the Permo-Carboniferous Periods.

The Tertiary ended with the Pliocene Period, when without doubt the climate of Europe was definitely warmer than at present. Towards the end of the Pliocene Period the temperature commenced to fall in Europe, and evidence of ice made its appearance. Some time between the end of the Pliocene Period and the present time, that is, geologically speaking, during the Pleistocene Period, there was a great extension of ice in all parts of the world.

The map (Fig. 1) shows the area which was under ice at some time or other during the Pleistocene Period. The north polar ice cap extended outwards, reaching latitude 38° N. in North America, 50° N. in Europe, and 60° N. in Asia. In the British Isles the ice sheet extended as far south as the Thames Valley but did not cross it. The ice covering of the Antarctic was then much thicker than at present, and Meinardus estimates that the flow of ice from the Antarctic continent into the surrounding seas was at least three times as much as at present.

Not only were the polar ice caps more extensive and thicker, but also the mountain glaciation was much developed and the glaciers reached much farther down the valleys. The evidence shows that this was so in all parts of the world. Not only were the mountains which now carry ice more heavily glaciated, but also many mountains which now carry no permanent ice had extensive glaciers upon them.

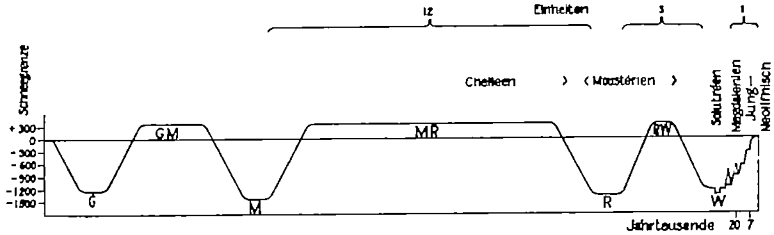

Fig. 2.

Penck and Brückner's diagram of height of snow-line in Alps during the Pleistocene ice age.

Detailed study of the deposits left behind by the ice shows that there was more than one advance and retreat of the ice during the Pleistocene Period. Glacial and interglacial epochs have been detected in all regions which were glaciated, both in regions covered by the extended polar ice caps and on the glaciated mountains. The history of the Pleistocene glaciation has been most completely studied by Penck and Brückner in the Alps. The result of their work is summarized in Fig. 2, which is a reproduction of their classical diagram showing the variation of the height of the snow-line in the Alps during the Pleistocene Period. From this diagram it will be seen that Penck and Brückner concluded that the snow-line descended far down the mountains on four occasions, the limits reached each time being practically the same, namely, about 1,500 metres (4,000–5,000 feet) below the present snow-line. They gave the names: Gunz, Mindel, Riss and Würm to the four glacial epochs. It will be noticed that the four glacial epochs occur in pairs—the Gunz with the Mindel and the Riss with the Würm—with a rather longer interglacial epoch between them.

There is no certain evidence that the history of the ice worked out in the Alps applies to other parts of the world; but meteorological considerations make it very improbable that there were different glacial histories for each part of the world; and as the evidence of glacial and interglacial epochs has been found wherever the glacial history of a country can be worked out in detail, one is justified in concluding that these epochs occurred simultaneously as the result of a world-wide cause.

This conclusion is becoming more and more accepted by glaciologists as they work out the sequence of the glacial epochs in their own regions, and a meteorologist cannot accept any other conclusion. In the sequel, therefore, we shall consider that the glacial history of the Alps is representative of the glacial history of the world as a whole.

The advance and retreat of the ice must have been accompanied by large variations in the climate. When a country such as Great Britain was invaded by an ice sheet, the climate must have been that of the polar regions to-day, and the fossils of plants and animals leave no doubt that such was the case. The climate during the interglacial periods, however, is much more interesting and unexpected. One would not have been surprised if the climate during the temporary retreat of the ice had remained cold and unpleasant. The evidence, however, is quite clear that in some, if not all, the interglacial epochs, the climate became warmer and more genial than to-day. At Hötting, in the Alps near Innsbruck, fossil leaves have been found of a rhododendron which grows to-day only in Portugal and the Caucasus, where the temperature is higher and the rainfall greater than it now is in Hötting; in the rivers of Europe (including the Thames) the shells of freshwater molluscs are found which now survive only in rivers such as the Nile, the temperature of which is 10° C. higher than that of the European rivers of to-day; and on the coasts of Holland and

Denmark, beds of sea shells were deposited containing species eighteen per cent of which to-day only occur south of the Bay of Biscay.

There is still considerable controversy as to which of the interglacial epochs these finds should be referred; so that we do not know whether all the interglacial epochs had warmer and wetter conditions than are experienced to-day. But there can be no doubt that in one or more of the interglacial epochs the climate not only returned to present-day conditions but also became warmer and wetter

Outside the areas which were invaded by the ice—the so-called glaciated regions—we must look to other records than those of ice to give us information regarding the changes of climate which occurred there during the advance and retreat of the ice. In non-glaciated regions it is difficult to find traces of changes of temperature; but changes in rainfall leave clear records in river deposits and in the levels of lakes with small or no outlets. From such evidence there is no doubt that there were long and pronounced periods of heavy rainfall during the Pleistocene Period in practically all parts of the world.

In North America the Great Basin, which is now an arid, sandy desert, was full of water, and the small existing intensely salt lakes were vast sheets of water to which the names Lake Bonneville and Lake Lahontan have been given. According to Gilbert and Russell, these lakes were twice filled during the Pleistocene Period, thus indicating that in North America there were two pluvial periods.

Wayland has reached the conclusion that in Uganda there have been two pluvial periods, one near the beginning of the Pleistocene Period and one towards the end; between these two pluvial periods the climate was much drier than it is to-day. Huzayyin has also recognized two major pluvials during the Pleistocene in south-west Arabia.*

Pluvial periods were not confined to tropical and subtropical regions, for in the Swanscombe Gravels we have evidence of a much greater Thames than exists to-day. The *Corbicula fluminaris* contained in these gravels show that they were laid down during an interglacial epoch when the temperature was considerably higher than at present.

Practically all deserts such as the Sahara, Libyan and Kalahara show signs of water action in relatively recent times, and many of them are littered with the flint tools of prehistoric man, showing that in the latter half of the Pleistocene Period they supported sufficient animal life to make them good hunting grounds.

It is probably too early to say definitely that in all parts of the world there were two pluvial periods, but the evidence is very strong, especially in North America and Africa.

The climatic conditions during the Pleistocene Ice Age may be summed up as follows:

The Pleistocene Ice Age did not consist of a simple advance and retreat of the ice but of a sequence of glacial and interglacial epochs. Based on observations in the Alps, there were four glacial epochs separated by three interglacial epochs. During some at least of the interglacial epochs the climate was warmer and wetter than to-day. In regions not subjected to glaciation there is evidence of two great pluvial periods, one early and one late in the Pleistocene Period, separated by a long interval during which there was even less precipitation than at present.

CAUSE OF THE PLEISTOCENE ICE AGE

A very large number of theories have been propounded to explain the cause of the Ice Age. It is becoming more and more generally accepted that no change located in the earth itself—such as a change in the distribution of land and water—or in the earth's atmosphere—such as a change in the amount of carbon dioxide or volcanic dust—can explain the sequence of climatic changes associated with the Pleistocene Ice Age, and we are being thrown back on to changes outside the earth. The most obvious source of climatic change would appear to be solar radiation. This seems such a simple solution. If we assume that the sun's radiation can change, all climates would appear to become possible: an Ice Age would be produced by reducing the radiation and a warm period by increasing it Unfortunately, things do not go in this simple way. As the result of a study which I made a few years ago to find what happens to the solar radiation when it falls on the earth, and how the earth returns to space the energy which it receives from the sun, I was led to the conclusion that the last Ice Age was not caused by a decrease of solar radiation but by an increase! I must now try to explain this paradox.

The sun sends out a stream of energy which we call sunshine. The earth intercepts a quantity of this energy which on absorption warms up the surface and the atmosphere. If the earth had been a 'black body' it would have warmed up to a temperature, which can be easily calculated, when it would have emitted just as much radiation as it received from the sun. In this way the temperature of the earth would have increased and decreased with an increase and decrease of the solar radiation. One of the first results of my investigation was to show that the earth does not react to changes in solar radiation like a 'black body'. I was able to show that if the solar radiation were to increase, the temperature of the earth's surface would not increase to anything like the extent that one would expect from the increase of solar radiation ; but that the cloud would increase and return the greater part of the additional solar radiation without warming up the surface of the earth.

---

* NATURE, 140, 518 (1937).

In this way the balance between the incoming and outgoing radiation is maintained more by the amount of cloud than by the temperature. In present conditions just about half the sky is covered by cloud ; the amount is slightly different in the different latitudes, but not to any large extent. The clouds appear bright because they reflect the sun's light. The light which the clouds reflect cannot be used to warm up the earth ; it is just returned to space, and to that extent the solar radiation is reduced. The amount of solar radiation returned directly by the clouds has been measured and proves to be 43 per cent of the total incoming solar radiation. That is, nearly half the solar radiation which reaches the earth is intercepted and returned by the clouds without taking any part in warming up the earth.

We will now consider what happens to the radiation which reaches the earth. Because of the shape of the earth, more solar radiation falls per square foot on the surface at the equator than at the poles. The equator is therefore maintained at a higher temperature than the poles. This difference of temperature causes differences of pressure in the atmosphere, and a circulation of air is set up between the equator and the poles. This is called the general circulation of the atmosphere ; and all winds ultimately can be traced back to differences of temperature, mainly those between the equator and the poles.

In the course of time the atmospheric conditions reach a steady state with a certain temperature distribution, a certain amount of air motion and a certain amount of cloud, which combined are just sufficient to cause a balance between the incoming and outgoing radiation.

Now let us consider what would be the effect of increasing the solar radiation by a specified amount. At first the increased radiation would reach the earth's surface and warm it up, but on account of the shape of the earth the equator would be warmed up more than the poles Hence the difference in temperature between the equator and the poles would be increased and this would lead to an increase in the general circulation of the atmosphere. The increased temperature and the increased wind cause an increase in the amount of water evaporated from the oceans. This increased water in the atmosphere leads to greater formation of cloud and, as the precipitation must equal the evaporation, to an increase in precipitation also.

The increased cloud, however, reacts on the solar radiation and reflects an increased proportion of it. The final state is a new balance between the incoming and outgoing radiation produced mainly by the increased amount of cloud, the only temperature change being that necessary to produce the greater amount of cloud.

Different parts of the world will be affected differently by these changes. In equatorial and temperate regions where the precipitation all falls as rain, the effects of increasing the solar radiation are simple : there is a slight increase of temperature and a general increase of rainfall. Thus the most important effect of increasing and decreasing the solar radiation is to increase and decrease the precipitation, and the two keep step with one another : a period of increased solar radiation is always a period of increased rainfall and vice versa.

When, however, we approach the poles, where the precipitation may be either in the form of snow or rain, the conditions are much more complicated and must be studied in more detail.

Let us fix our attention on a region where at present the summer temperature does not rise above the freezing point, so that there is little or no summer melting of the ice—the Antarctic is such a locality. Now let the solar radiation increase. In consequence, the precipitation and the mean annual temperature both increase, as indicated by Curve I of Fig. 3. At first all the precipitation is in the form of snow, but when the summer temperature approaches the freezing point—say, at *A*—some of the summer precipitation falls as rain. Curve II represents the annual snowfall, and as the radiation increases beyond the point marked *A* the curve for snowfall falls increasingly below the curve for the total precipitation. Curve III represents the evaporation and summer melting combined. At first there is no melting, only evaporation, but after *A* melting becomes more important, and at *B* the loss of ice through evaporation and melting equals the total snowfall. Curve IV in the lower half of the diagram represents the annual accumulation of snow ; it is obviously the difference between Curves II and III. At first, the annual accumulation of snow is small ; as the solar radiation increases, the accumulation of snow increases until it reaches a maximum, after which it rapidly decreases, owing to the rapid increase in the amount of melting. Finally, in spite of the greater total precipitation and large annual snowfall, the melting is so great, especially in the summer, that no accumulation at all takes place.

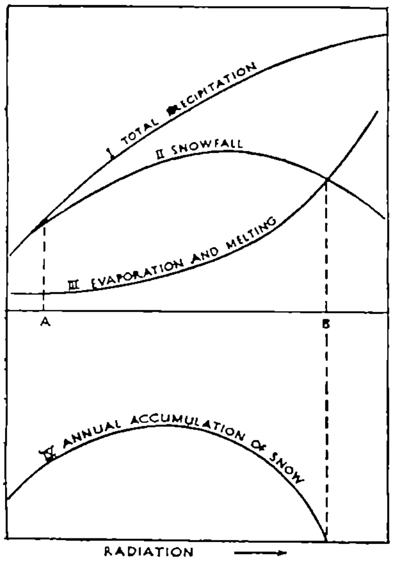

Fig. 3.

EFFECT OF INCREASING RADIATION ON PRECIPITATION AND ACCUMULATION OF SNOW.

Although it may seem strange that an increase of temperature can produce increased glaciation, it may be demonstrated by a simple experiment. In four identical glass jars (Fig. 4) each containing a layer of water in the bottom and a metal vessel at the top which can be cooled by solid carbon dioxide, the water at the bottom represents the equator and the metal vessel at the top the polar regions. One jar (second from the left) contains water at the temperature of the room and there is an appreciable deposit of ice at the top. By adding ice to the water in the vessel to the left, equivalent to lowering the equatorial temperature, the deposit of ice at the top is much reduced. The water in the third vessel has been warmed by a small gas jet, and the effect of the heating has been greatly to increase the deposit of ice. In the fourth bottle the temperature has been raised still higher, with the consequence that the ice has almost entirely disappeared by melting.

These four bottles can be regarded as representing increasing radiation as shown in Fig. 3. The first bottle has a low temperature (little radiation) and the ice deposit is thin, corresponding to *A* on the diagram. The second bottle has a higher temperature (more radiation) and therefore corresponds to a point to the right of *A* on Fig. 3 and shows a greater accumulation of ice. The third bottle represents the conditions where the ice deposit reaches its maximum, and the fourth bottle represents some point beyond *B* where the melting and evaporation exceed the deposit.

The conditions represented by Fig. 3 and the experiment apply to the polar regions and high mountains. At first an increase of solar radiation causes an increased accumulation of snow and ice in spite of increased temperature. During this stage, ice sheets form and glaciers advance, giving rise to a glacial epoch. As the radiation increases still further, the ice melts away and we have overcast skies and much precipitation but no ice accumulation. When the solar radiation decreases, conditions are reversed and the whole sequence is gone through in the reverse order.

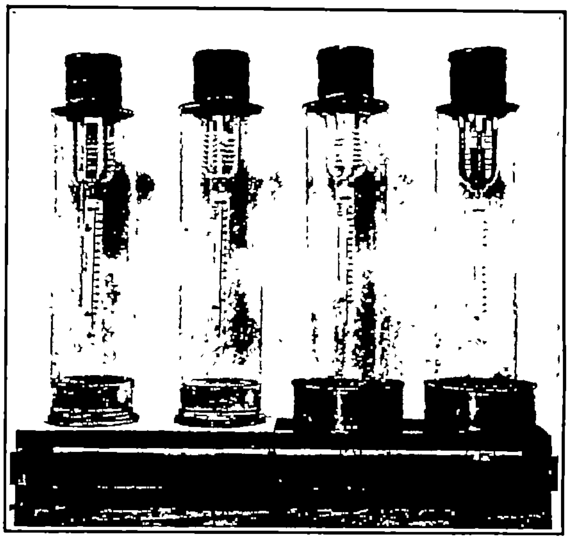

Fig. 4.

EXPERIMENT SHOWING EFFECT OF INCREASE OF TEMPERATURE ON AMOUNT OF ICE FORMATION. TEMPERATURE OF WATER AT BOTTOM OF BOTTLES INCREASES FROM LEFT TO RIGHT.

Fig. 5 has been prepared to show the sequence of changes of ice and meteorological factors when the solar radiation makes two complete oscillations. The abscissæ represent time increasing towards the right. Curve I represents two complete cycles of solar radiation and Curve II represents the mean temperature of the world as a whole. Curve III is the curve of precipitation and therefore follows directly the curve of solar radiation. Curve IV is the curve of snow accumulation. As drawn, it shows some accumulation at the minima of the solar radiation, but a complete disappearance of the accumulation owing to increased temperature at the maxima of the radiation. The ice which accumulates year by year in the specified area must escape; if the area is a mountain top, the escape will be by way of glaciers; if it is a polar cap, the escape will be by an ice sheet spreading over the surrounding country. In either case the ice is transported into regions where the melting is greater than the snowfall, and the greater the annual accumulation the farther will the ice penetrate, down the mountain side if a glacier and into lower latitudes if an ice sheet. Curve V shows the advance and retreat of the ends of the glaciers or of the front of an ice sheet.

Examining the last curve, we see a close resemblance to Penck and Brückner's curve for the height of the snow-line in the Alps (Fig. 2). In each there are four advances of the ice. The advances are arranged in pairs, with short interglacials between the advances in the pairs, and the pairs separated by a longer interglacial. This arrangement comes from the fact that there are two glacial epochs for each maximum of the solar radiation. The interglacials have different climates according as they occur at the maximum or a minimum of the solar radiation. The former are warm and wet and the latter are cold and dry. We are at present approaching a minimum of solar radiation. In consequence our rivers are smaller and our temperature lower than they were in the last interglacial. We now see why there were only two pluvial periods in non-glaciated regions for the four glacial epochs in polar regions and on mountains. If the theory is correct, the last interglacial—the Riss-Würm interglacial—was a warm one, and to it the evidence for a warm wet climate which I have described above should belong.

Thus we see how two oscillations of radiation have produced in non-glaciated regions two pluvial periods, and in glaciated regions four glacial epochs separated by three interglacial epochs, two of which were warm and wet and one cold and dry. If the theory is correct, we are now living in a cold dry epoch owing to the decrease of solar radiation from its last maximum. If the solar radiation again increases, there will be another glacial epoch and our epoch will become a second cold dry interglacial.

An obvious objection to the explanation of the last Ice Age which I have given above is that with their present temperatures no amount of precipitation would result in the formation of an ice sheet over England and Scotland and still less over Ireland; yet we know that such ice sheets did exist. The objection is still stronger when it is remembered that the theory requires the increase of precipitation to be accompanied by an increase of temperature.

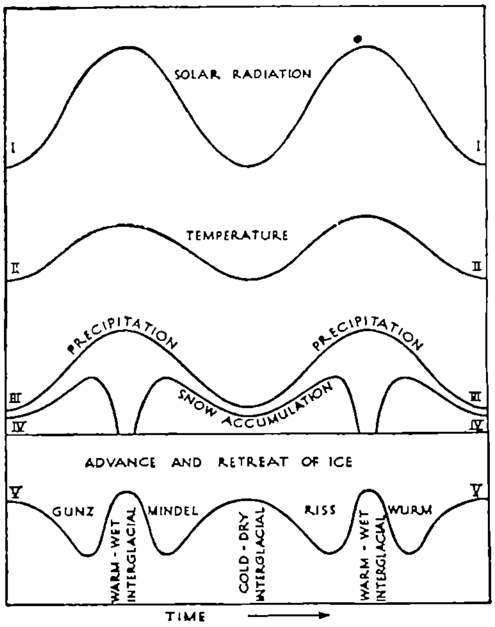

Fig. 5.

Effect of two cycles of solar radiation on glaciation.

There is another problem which has puzzled everyone who has studied the cause of the Ice Ages. If we plot on a circumpolar map the limits of the ice sheet, we find that the area covered by the ice was not concentric with the North Pole. It extended much farther south over Europe and the east of North America than it did over Asia and the east of America; in fact the centre of the ice sheet was in the middle of Greenland, 20° of latitude from the Pole.

The answer to both these problems is the same and gives strong support to the correctness of the theory. If the area around the North Pole were land instead of sea, we should have at the Pole a great ice sheet, similar to that over Greenland and the Antarctic, rising many thousands of feet above sea-level. With increased precipitation this ice cap would increase in height and extent and grow symmetrically about the Pole. With the present distribution of land and sea such a north polar cap is not possible. The ice which forms in the Arctic Ocean during winter breaks up in the summer and a certain amount escapes into the North Atlantic Ocean. At the maximum of a glacial epoch when the coasts around the Arctic Ocean were under ice, there would be a great flow of ice throughout the year into the sea The whole Arctic Ocean would become packed with ice which would have to find an outlet somewhere. The Bering Strait between Asia and America is both narrow and shallow, and no appreciable amount of ice would escape that way. There was always, however, a wide, deep connexion between the Arctic Ocean and the Atlantic Ocean between Greenland and Norway. Through this passage icebergs and thick pack ice would move southwards, filling the North Atlantic with ice and lowering the temperature.

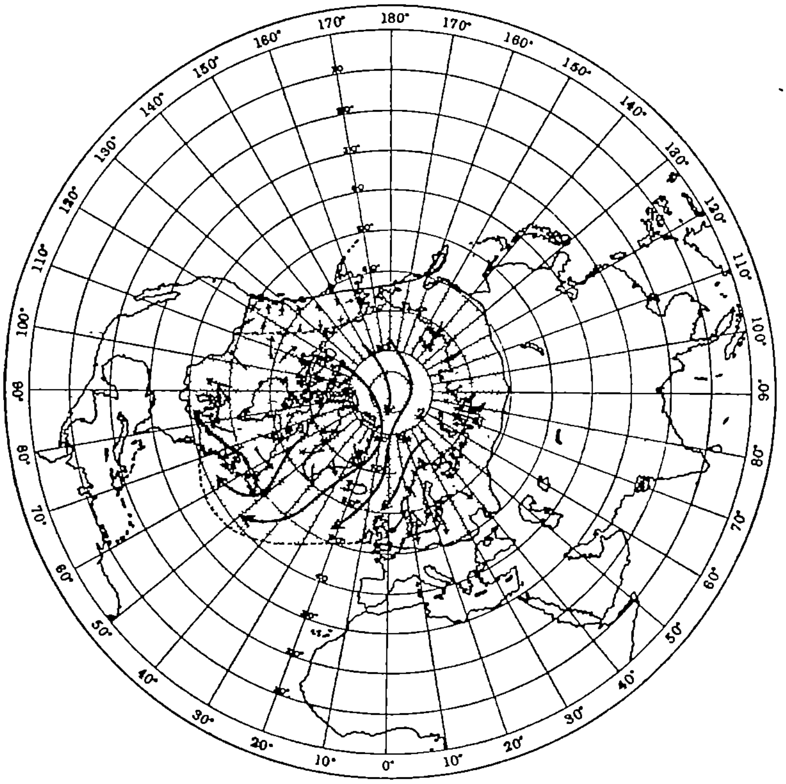

Fig. 6.

Lines of flow of ice: thick arrows floating ice, thin arrows land ice.

Fig. 6 has been drawn to illustrate this. The ice-covered area has been stippled and it will be seen at once that this area is not concentric with the Pole. The flow of ice on the land is shown by thin arrows. Ice flows into the Arctic Ocean from the northern coasts of America and Asia, and moves, as shown by the long thick arrows, into the North Atlantic, where it is replenished by ice from Greenland and Norway, and a stream of ice passing down Davis Straits joins it to the south of Greenland. The whole of the North Atlantic was filled with ice.

These conditions would have far-reaching effects on the climate of the British Isles and the adjacent parts of Europe. In the first place the Gulf Drift would no longer exist, so that instead of the western coasts of Europe being washed by relatively warm water they were washed by cold seas dotted with ice. In the second place the Icelandic depression would either cease to exist or would be displaced to the south, so that the warm south-westerly winds to which we owe our mild climate were replaced by cold north-westerly winds. With these large changes there is no wonder that ice sheets formed on the British Isles. On the American coast the winds would be north-east and drive the ice-laden water on to the American coast. Thus glacial conditions extended far to the south on both coasts of the Atlantic Ocean. As there was no corresponding flow of ice into the Pacific Ocean, there was no similar glaciation of the Pacific coasts.

Thus the glaciation of the British Isles and the unsymmetrical position of the ice sheets relative to the Pole were both due to flow of ice from the Arctic Ocean into the North Atlantic. If this connexion had not existed, the distribution of the ice would have been quite different.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST ALBANS

July 1936, and is still producing at the rate of approximately 10 barrels a day. Another situated half a mile south-east gave a 30-barrel show of oil in the Bartesville Sand in 1922; and a third, a considerable distance to the north-east of the other two, produced about 25 barrels of oil in 1921. The presence of productive oil sand in these three wells points to the probability that oil-bearing Bartesville Sand occurs in this district in a characteristic lens-shaped body. In addition, there are known to be in the Reservation two small domes, as yet untested, but structurally similar to two nearby domes producing from the Siliceous Lime. The productive domes are fairly typical of the oil fields, being of small extent but giving large yields. On one of these there are eight wells which have yielded oil, and on the other five. The approximate yield per acre of the former dome up to July 1936 was 6,964 barrels of oil, and of the latter, for the same period, 6,300 barrels. Recently, also, the rate of yield from both domes has been materially increased by treating the oil-bearing beds in the upper part of the Siliceous Lime with hydrochloric acid.

Plastics and Insulation

A JOINT meeting of the Institution of Electrical Engineers and the Plastics Group of the Society of Chemical Industry was held at the Institution of Electrical Engineers on March 24 to discuss a paper on "Plastics and Insulation" by L. Hartshorn, N. J. L. Megson and E. Rushton. It is largely based on an investigation carried out at the National Physical Laboratory and the Chemical Research Laboratory for the British Electrical and Allied Industries Research Association. Broadly speaking, a plastic is any material from which rigid objects of predetermined shape may be made by moulding processes. Their most characteristic property is that by suitable treatment they may be made to pass through a plastic condition, that is, a state between the solid and liquid states, like that of dough or damp clay. The property of hardening instead of softening on the application of heat is one of considerable practical importance to both moulders and users of plastics. It increases the working temperature of the material and improves its mechanical properties. It also allows the finished article to be removed from the mould while still hot. The primary function of an electrical insulating material (a dielectric) is to act as a barrier to the flow of electricity. Dielectrics always pass a leakage current, sometimes through the body of the material and sometimes over its surface. These currents can be taken as a measure of a defect of the material. With alternating current we have in addition an expenditure of energy due to the pulsating current in the dielectric. Polystyrene and polyindene, materials not yet produced in Great Britain, are hydrocarbon plastics, made in the form of clear glass, like solids, and are almost ideal for use in cables for high-frequency work; for example, in television, and in ultra-short-wave radio work, and in junctions for high-voltage cable work they are almost ideal.

Report on Street Lighting

DR. J. W. T. WALSH gave an introductory account to the Illuminating Engineering Society on February 8 of the final report of the Ministry of Transport Committee. It was then discussed by the Society and the discussion is published in the February issue of *Light and Lighting*. The members constituting the Committee were the chairman, four lighting specialists, two engineers associated with local authorities and two Government officials. Its final report was issued in November 1937. The Committee received evidence from several organizations and made inspections of a large number of existing installations. It also carried out experimental work on a special roadway (Lonsdale Road, Barnes) set aside for the purpose. The Committee classified roads into two groups only, A and B, and gave technical recommendations for each group. In the recommendations the Committee insisted on the importance of satisfactory maintenance and approved of lighting from dusk to dawn. Whilst it was recognized that special study of measures for the guidance of traffic during fog was necessary, it was urged that the general design of installations should not be prejudiced by special adaptation to fog conditions. The report also recommends that a formal specification for street lighting should be issued without delay by the British Standards Institution. In conclusion, Dr. Walsh showed a film of a lighted street just as it would appear in practice, in which various objects (persons stepping into the roadway, dogs, etc.) were continually coming into view and then disappearing. The number of such disappearances was stated to be fifty-six. But very few of the observers succeeded in identifying half this number. This showed the danger of bad lighting.

Journal of Neurophysiology

THE new *Journal of Neurophysiology*, under the editorship of Prof. Dusser de Barenne, J. F. Fulton and R. W. Gerard, made its first appearance in January. It is designed primarily to provide a means of publishing papers dealing with the experimental analysis of the phenomena of the central and peripheral nervous system, and descriptive neuroanatomy and pathology are intentionally excluded. The publisher, Thomas of Springfield, Illinois, intends to produce a number every other month, and the editorial board undertakes to deal with submitted papers within one or two months of receipt. This accelerated publication is certainly desirable, as the existing channels for the publication of papers in this field in the United States are overcrowded, and there is an inevitable delay. The first number, of 55 pages, contains nine papers dealing, *inter alia*, with cerebral action potentials, effects of experimental cerebral lesions, degeneration of nerve, and changes in the salt content of nerves as a result of the transmission of impulses. The format is pleasing, and the standard of the illustrations is high. A little more uniformity in certain details is desirable; authors are cited in different papers either by numbers, by year or by an abbreviation of the year; the date of receipt of papers is not always given. A more uniform lettering of the illustrations might also receive attention, and the adoption of a bold face type for the volume numbers in the lists of references would add to the ease of reading. These criticisms are, however, minor and are points which will probably be dealt with as the journal becomes more mature. The periodical certainly fills a need, and should serve, as the editors point out, actually to help to counteract undue subdivision in physiology by bringing together in one journal many divergent investigations on the nervous system.

Social Applications of Physics

IN an address on the "Social Applications of Physics" at a symposium at the University of Sydney on September 21, which was published in the *Union Recorder* (October 7), Prof. O. U. Vonwiller, pointing out that the man of science to-day must consider the bearing of his work on the problems of civilization and recognize his responsibility for some of the economic and social difficulties of the times, suggested these difficulties were due primarily to our inability to accommodate social and economic conditions to the rapidly changing methods of production following the application of scientific discovery. The main cause of these rapid changes was the changed status of the inventor, and while the success of the man of science as inventor had brought many real benefits to mankind, much distress had also arisen because in applying scientific discovery the first consideration was that of financial benefit. Prof. Vonwiller considered we could not continue to ignore ameliorating measures and suggested that the most promising method for dealing with the evils of over-production was to reduce the hours of employment. No satisfactory and lasting improvement in our difficulties could be expected, however, unless we adopted much from the methods of scientific investigation and discovery, with their honesty of inquiry and statement. In economic questions the difficulty of avoiding prejudice, however, was very great, and Prof. Vonwiller did not suggest that the adoption of scientific method would remove all our difficulties, though he appealed strongly for a courageous endeavour to understand and make understood the possibilities and limitations of scientific progress.

Twenty-fifth Anniversary of Laue Diagrams

LAUE first used his method of X-ray analysis of crystal structure in 1912. The twenty-fifth anniversary of this event has been celebrated by *Die Naturwissenschaften* by the publication of two interesting articles on the progress made in this branch of crystal chemistry. One, by F. Laves (*Naturwiss.*, 25, 705, 721; 1937), deals with the theory of the method and its development, and mentions its applications, particularly to the determination of atomic distances in crystals. A full account of our present knowledge of the radii of ions and atoms and their separations in crystals, and the dependence of these on the type of linking, is given, and there is a useful bibliography. The second article deals with the use of X-ray interference methods in the investigation of the fine-structure of animal tissues, and is contributed by F. O. Schmitt (*Naturwiss.*, 25, 709; 1937). It mentions particularly progress made in the examination of nerve, sinew and muscle, and other tissues in which there is a high degree of orientation of proteins or lipins. It will be recalled that *Current Science* also had special articles in connexion with this anniversary (see NATURE, 139, 517; 1937).

History of Science and Medicine

WE have received the fourth volume of *Osiris*, a journal edited by Dr. George Sarton and dealing with the history and philosophy of science. This volume is entitled "Incunabula Scientifica et Medica", by A. C. Klebs, and contains the titles of books on science and medicine printed up to the year 1500, with references to catalogues indicating where the books may be found. This list is very convenient to students of the history of science and medicine, since it contains information which was previously to be found only in large and expensive library catalogues. The volume is quite a substantial one, having 359 pages, so that it is evident that an unexpected range of material of this class was printed at an early period. In a book purporting to give accurate information on dates of publications, it is somewhat surprising to find the title-page dated 1938, whereas the volume was received in October 1937.

Proposed List of Current Geographical Publications

MORE than eight hundred technical and scientific periodicals are received by the library of the American Geographical Society. From these a careful selection of material of geographical interest is made, to be entered in the library's research catalogue. A current index is thereby provided to an extremely important body of geographical material that does not appear in the usual library catalogue. There is thus afforded a continuous, up-to-date record of current material of value not only to geographers but also to geologists, economists, anthropologists, and workers in many other allied fields. So useful has the research catalogue proved to the staff of the Society and to those consulting its library that the Society now proposes to make this material more generally available if there is sufficient demand. It is planned to publish ten mimeographed lists a year of the material catalogued during the month (material for July and August to be listed in the following issues). The subscription rate will be 3.75 dollars.

Fisheries Research in Australia

THE 138-ton motor ship *Warreen* (an aboriginal name for the sea), built for the fisheries section of the Australian Council for Scientific and Industrial Research, has been launched in Melbourne. The vessel will be used for the study of pelagic fish in the waters around Australia, commencing in the south-eastern seas. The headquarters of the section will be at Port

Hacking, some eighteen miles south of Sydney, on a reserve beautifully situated for the purpose. Plans have been drawn for a laboratory to cost £12,000, which should be finished by the end of the year.

International Society of the History of Medicine

The eleventh Congress of the International Society of the History of Medicine will be held in Yugoslavia on September 2–11 at Zagreb, Belgrade, Serajevo and Ragusa. The stay at Ragusa will coincide with the birthday fête of the King, who will be patron of the Congress. The following subjects will be discussed: (1) the history of medicine in different countries, introduced by Prof. Gomoiu; (2) the history of malaria in the Balkan peninsula and especially in Yugoslavia; (3) natural history in popular medicine (animals, plants, minerals); (4) mystery and magic in popular medicine; (5) medicine in folk poetry; (6) psychogenic diseases and psychotherapy in popular medicine. Further information can be obtained from the general secretary, Dr. Vladimir Bazala, Vlaska Ulica 95, Zagreb, or from Dr. Guiart, 58 Boulevard de la Croix Rousse, Lyon.

Schools and the Way to Peace

An international conference of teachers to be held in London on April 22–25 is being organized by the Education Committee of the League of Nations Union. It is intended to re-examine the whole question of 'peace teaching' in the schools in view of recent changes in the international situation in Europe and the Far East. The opening session will be in University College and the closing session at Guildhall, where members will be entertained to luncheon in the crypt. Other sessions will be in the London School of Economics and Political Science, and there will be an afternoon reception by the Vice-Chancellor of the University in the Senate House. Among those who will take part in the conference are the Duchess of Atholl, Lord Cecil, Lord Allen of Hurtwood, Prof. Gilbert Murray, Mr. Kenneth Lindsay and Mr. H. G. Wells. The last-named is to speak at a public discussion on "The Teaching of History". In connexion with the conference, a schools' poster competition has been organized with the object of advertising the value of the League of Nations and the International Labour Organisation as a means of securing the improvement of social conditions and of human welfare through international action. Further particulars can be obtained from the L.N.U., 15 Grosvenor Crescent, S.W.1.

Announcements

The Forestry Commissioners have appointed a committee, under the chairmanship of Lieut.-Colonel J. C. Wynne Finch, to advise them about the suitability of the Forest of Dean as a national forest park. Mr. Frank H. Harris and Mr. E. S. J. Hinds, Forestry Commission, 55 Whitehall, London, S.W.1, are joint secretaries to the Committee.

The Linnean Society of London will celebrate the one hundred and fiftieth anniversary of its foundation on May 24–26. The president, Dr. J. Ramsbottom, will deliver an address on May 24 at 6 p.m., and on May 25 and 26 symposia on "The Concept of Species from the Time of Linnæus to the Present Day" will be held. Further information can be obtained from the Assistant Secretary, Linnean Society, Burlington House, Piccadilly, London, W.1.

Flying Officer A. E. Clouston and Mr. Victor Ricketts arrived at Croydon on March 26, having accomplished a return flight between England and New Zealand (about 24,000 miles) in 10 days 21 hours. This is the first time that a direct double flight has been made, and several new records were set up. The aeroplane was the de Havilland Comet which won the international air race from London to Melbourne in 1934.

Prof. Camille Gutton, of the Ecole Nationale supérieure de l'Aéronautique and the Ecole professionnelle supérieure des Postes et Télégraphes, Paris, has been elected a free academician of the Paris Academy of Sciences, in succession to the late Paul Janet.

The first International Congress of Cosmobiology, organized by the Société médicale de Climatologie et d'Hygiène du Littoral Méditerranéen, will be held on the Côte d'Azur on June 2–8. Prof. D'Arsonval will preside over the radiological section and M. Lumière over the biological section. Further information can be obtained from the secretary, 24 rue Verdi, Nice.

The following have recently been nominated members of the Imperial Leopold Caroline German Academy at Halle: Dr. Matsujiro Takenouchi, professor of bacteriology at Tokyo, Dr. Antonio Dias Albertini, president of the Finlay Institute at Havana, Dr. Sven Petrus Ekman, professor of zoology at Uppsala, Dr. Mokoto Ishiwara, professor of physiology at Fukuoka, Japan, Dr. Gustav Senn, professor of botany at Basle, and Dr. S. P. L. Sørensen, head of the Carlsberg Institute at Copenhagen.

Reprints of fourteen papers by Mr. T. S. Subbaraya, Central College, Bangalore (University of Mysore), and his collaborators, published between 1929 and 1937, have been received. Particular acknowledgment is made of indebtedness for the help and collaboration of Prof. B. Venkatesachar, professor of physics in the University. The scope of the papers is too wide to permit of description in a short paragraph. The topics divide themselves almost completely into two classes, one dealing with nuclear structure and nuclear magnetic moments, and the other with problems in spectroscopy. In the latter category is a series of important papers on the spectrum of ionized mercury. There are papers dealing with the spectrum of ionized zinc, and with the band spectra of cadmium, zinc, cadmium iodide, and mercurous iodide. An early paper discusses the range of distinct vision of the unaided eye under water.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 610.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Aerial Drift of Insects

SINCE the summer of 1932 the distribution of insects by aerial currents has been studied in this Department. The present communication concerns the experiments made with kites over the land; investigations over the sea were briefly reported last year[1]. The methods employed have been borrowed from oceanography and inverted. Tow-nets, with a three-foot diameter mouth, have been carried into the air by kites to heights ranging from 150 ft. to 2,350 ft. The nets were sent up closed, opened automatically at the desired height, and closed again at the end of the sampling period before being hauled down. 82 samples were obtained, yielding 839 insects in a total collecting time of 124½ hours from May until September.

Fig. 1 shows the average density of the aerial population based on more than 10 hours collecting in each of the height ranges: 150–300 ft., 300–500 ft., 500–750 ft., 750–1,000 ft. and 1,000–2,000 ft. The curve represents the average number of insects taken per 10 hours collecting with our standard 3-foot diameter net in each height range and the scale of dots represents the average number of insects at each height drifting over a 10 *yards frontage* in an hour; each dot represents a hundred insects. It shows clearly the aerial food available for swifts and swallows. Incorporated in the curve are values (*T*) obtained from an intensive study of the insect drift at lower levels made by Mr. J. A. Freeman using nets flown simultaneously at heights of 10 ft., 177 ft. and 277 ft. on each of three masts over a 5/6 mile frontage at the Beam Wireless Station at Tetney, Lincolnshire.

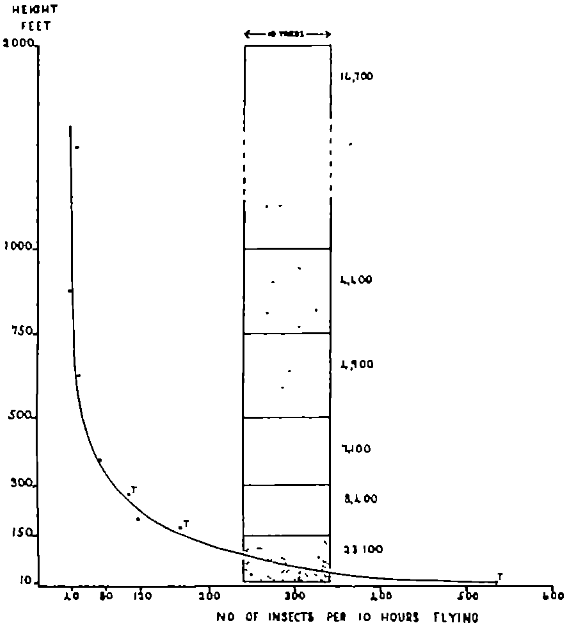

Fig. 1.

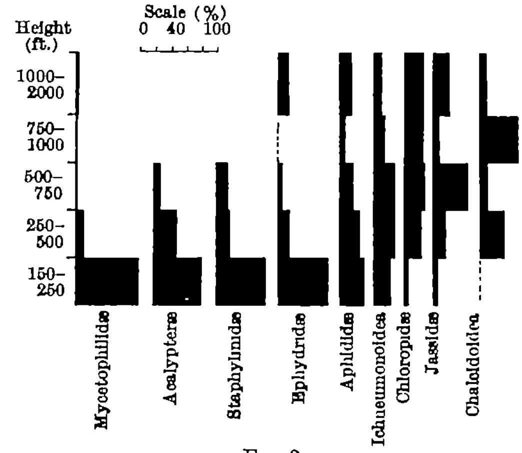

Fig 2.

The 'aerial plankton' is made up essentially of small light-bodied insects with weak powers of flight, but with a relatively large wing surface compared with body mass. Fig. 2 shows the comparative vertical distribution of the nine more important families encountered between 150 feet and 2,000 feet; the average number of any one family per 10 hours collecting in each height range is shown as a percentage of the total of that family taken (per 10 hours collecting) at all height ranges. Nearly all the families recorded in the aeroplane collections of Collins and Baker[2] in America and Berland[3] in France have been taken in our kite nets.

Whilst different insect groups are shown to be influenced somewhat differently by atmospheric conditions, it is found for all that high temperature and low humidity are more favourable to aerial drift than the reverse conditions.

Among agricultural pests, the frit fly, *Oscinis frit* Linn., was taken on many occasions up to 600 feet, thrips up to 450 feet and aphides, including the grain aphis *Macrosiphum granarium* Kby., up to 1,600 feet. That so many insects have been taken over the sea when more than a hundred miles from land[1] emphasises the importance of wind drift in the dispersal of insect pests both from one part of the country to another as well as the infection of Great Britain from the continent. Whilst migrating birds may well be the carriers of foot-and-mouth disease, the possibility of insects also being the carriers should not be overlooked.

With the kind co-operation of the London and North Eastern Railway a study of the varying abundance of insects along a line of country was begun last summer by using collecting nets on railway trains between York and Hull. By changing the nets at definite points along the line and repeating the lines of observation throughout the summer, the variations in population densities have been studied in relation to meteorological data. Marked distributional changes are observed over quite short periods of time. It is hoped that the experiments may be extended over a wider area in the future.

A first full report will be published in the *Journal of Animal Ecology*.

Distorted Mountain Strata in Relation to Final Isostasy

ISOSTATIC equilibrium ensues only after disturbances have ceased. The strata of mountains must originally have been deposited horizontally. They may be held to have attained to heights much greater than now exist. As they accumulated locally gravity would be disturbed by their weight, and if they rested on a much deeper foundation of slightly viscous but more dense material they would gradually sink down into it until they floated in hydrostatic equilibrium. It is assumed that this sinking is a slower process than the deposition of the strata. As the result, if a level datum surface is imagined as traced in the viscous foundation, at a level below the sunk roots of the deposited strata, hydrostatic equilibrium along it requires that the weight of material in all columns standing on this surface should be uniform. This is the observed isostasy; thus, beneath a more elevated region its roots of lighter density would penetrate deeper and so compensate the extra column aloft. The depths of these floating roots should even exceed the heights of the elevations, so the height of the original deposited strata would have been much greater than that of the present compensated mountains. In the deep sinking of such horizontal local strata they would be broken up, with result reminiscent of the distorted fragmentary mountain strata that are observed. But an analogy to the breaking up of an Arctic ice-floe would be excessive.

This order of ideas may doubtless be entertained with reluctance, but it appears to offer the only path by which the actual recognized degree of isostasy can have been arrived at. For the case of a linear mountain range the sinking of the strata would be smoother on the two sides of the central axis. It may be that the main part of the mass has been pushed up from below, but it has still to fall back into isostasy, which any sedimental part clinging to it will show by warping.

After an inconclusive survey by Bouguer in the Andes, the earliest effective exploration in that direction was by Maskelyne and Cavendish on the wedge-shaped isolated mountain Schiehallien in Scotland, made with a view to estimating the mean density of the earth from the deviation of the plumb-line by the horizontal attraction of this mountain mass of perhaps roughly ascertainable density. If the mountain rests on floating roots less dense than the average the horizontal attraction would thereby be diminished, so that the apparent result for the earth's mean density would be increased from the true value: but actually the result was considerably less. Formal isostatic discussion was initiated from the early surveys of the corps of Royal Engineers in the Himalayas as analysed by Archdeacon Pratt of Calcutta. They revealed defects of density beneath the mountains. The principle of compensation was more recently extended as a working hypothesis to the whole earth, mainly by Hayford in America. It is now submitted that the undoubted facts of isostasy may provide the clue, however unexpected, to the inner mystery of mountain structure, so that only the later stages of mountain carving are due to atmospheric denudation.

Coenzyme of the *d*-Amino-acid Oxidase

IT has been shown by Das[1] that the soluble amino-acid oxidase of Krebs[2] requires for its activity the co-operation of a thermostable factor or coenzyme which can be obtained from animal tissues and from yeast.

The object of this investigation was to determine the nature of this factor. This could only be achieved after separation of the enzyme system into its two components: the thermolabile enzyme and thermostable coenzyme, followed by their purification. While this work was in progress, Warburg and Christian[3] announced in a preliminary note that they have succeeded in separating this enzyme system into its two components, and in purifying the coenzyme. They have not, however, revealed their method of preparation and purification of these components.

I propose to give here the main results of my work on amino-acid oxidase, together with a description of the methods used in the preparation and purification of the enzyme and coenzyme.

Preparation of Enzyme. Finely powdered acetone-dried pig's kidney is extracted with 20 vol. water and the insoluble residue centrifuged off. To each 100 c.c. solution is added 1 gm. tricalcium phosphate gel, which is centrifuged off together with adsorbed inactive protein. To every 100 c.c. of this solution is added 22 gm. ammonium sulphate, and the mixture left standing 12 hours at room temperature. The precipitate is dissolved, reprecipitated in the same way, redissolved in water, dialysed and centrifuged. The solution is adjusted to *p*H 6·5, the enzyme is adsorbed on alumina gel (*A*) and eluted with phosphate buffer *p*H 7·8, giving an almost colourless solution of enzyme, inactive in absence of coenzyme but highly active ($Q_{O_2} = 1{,}000$) in its presence, and oxidizing the unnatural isomers of alanine and proline.

Preparation of Coenzyme. Horse heart muscle is minced and washed twice in 10 vol. tap water. 1 kgm. of washed mince is extracted with a mixture of 850 c.c. acetone and 150 distilled water at 50° C.

The warm mixture is pressed through muslin, cooled, filtered with kieselguhr, treated with 0·5 c.c. concentrated ammonia and concentrated to 20 c.c. The solution is then treated with 50 c.c. acetone and 0·5 c.c. acetic acid. The precipitate is removed and the solution mixed with 200 c.c. acetone. The precipitate, which contains the coenzyme, is dissolved in 5 c.c. water, centrifuged, and the clear solution treated with 50 mgm. barium acetate and 10 c.c. ethyl alcohol. The precipitate is collected, decomposed with 2–3 c.c. dilute sulphuric acid, the barium sulphate centrifuged off and the coenzyme solution precipitated by 10–15 volumes acetone.

This yellow powder which contains the coenzyme is readily soluble in water, but insoluble in organic solvents. It is precipitated by salts of mercury, lead and barium, but not by calcium, even in the presence of 2 vol. alcohol. It is very unstable in acid solution but not affected by weak alkali. A slightly alkaline solution of coenzyme has a characteristic yellow colour with the greenish fluorescence of flavines and a spectrum similar to that of lactoflavine. The colour disappears on reduction with $Na_2S_2O_4$ and reappears on shaking the solution with air.

2·5 kgm. heart muscle yields about 12 mgm. of very active coenzyme containing about 20 per cent flavine.

The activity of the reconstructed system tested ærobically in Barcroft differential manometers is shown in the following table:

OXYGEN ABSORPTION IN AIR AT 39°.

	1	2	3	4
Enzyme solution	1·0	1·0	1·0	1·0
M/10 phosphate buffer *p*H 7·8	2·0	2·0	2·0	0·2
3·3 per cent *d*,1-alanine solution	0·3	0·3	0·3	0·3
Coenzyme, added in buffer sol.	—	1·5γ	3·0γ	6·0γ
c.mm. oxygen absorbed in 10 min.	1·0	34·5	63	105
c.mm oxygen absorbed in 20 min.	2·8	69·0	124	207

While in presence of enzyme and substrate only, methylene blue (0·5 c.c.; 1 : 5,000) is not reduced anaerobically even in 12 hours; on addition of coenzyme (10 γ) it becomes reduced in about 27 minutes.

The fact that the flavine content of coenzyme preparations was proportional to their activity supports the view that the flavine is a part of the active compound. It is conceivable that the coenzyme is related to a compound containing 40 per cent flavine isolated by Theorell, Karrer, *et al.*[4] from animal tissue, a compound which has different properties from phosphoric esters of flavine obtained synthetically or isolated from yeast.

The ubiquitous presence of the coenzyme described in tissues, where no deamination is observed, suggests that it can also play an important part in other oxidation reactions of the cell.

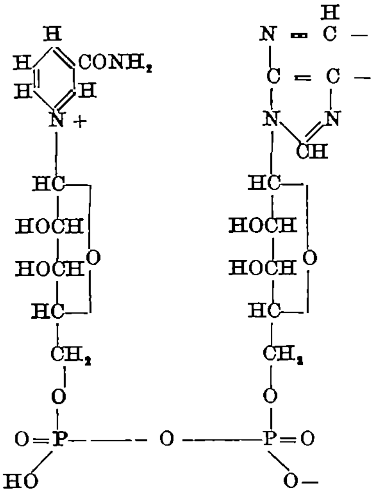
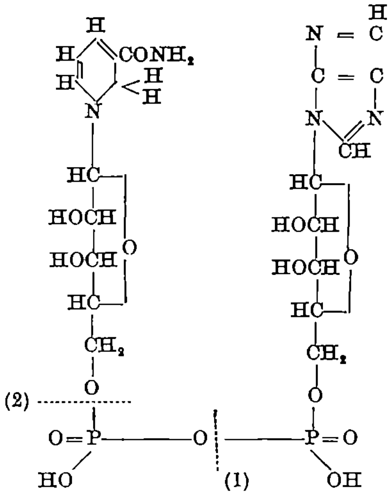
Enzymic Dephosphorylation of Cozymase

FOLLOWING the observations[1,2,3] that cozymase is inactivated by vegetable as well as animal tissues it was considered to be of interest to study the mechanism of inactivation. Euler, Adler, Günther and Hellstrom[4] found that cozymase was inactivated by dialysed muscle extract, but that the latter was active in glycolysis only when cozymase and adenylic acid were added. They concluded that no adenylic acid was formed and suggested that the inactivation of cozymase might possibly be due to dephosphorylation. The present investigation shows that cozymase is rather slowly dephosphorylated by nucleotidase which dephosphorylates adenylic acid and inosinic acid much more rapidly (the former more easily than the latter). On the other hand, dihydro-cozymase is dephosphorylated about twice as fast as cozymase. In animal tissues cozymase is present in the oxidized as well as in the reduced form, and the present observation might suggest some biological indications.

According to Euler and Schlenk, the cozymase molecule is as follows:



Cozymase



Dihydro-cozymase

Considering the biological functions and structure of cozymase as well as dihydro-cozymase, it might be suggested that dihydro-cozymase is capable of being split enzymatically[4] at position (1) to adenine nucleotide and nicotine nucleotide and that the enzyme nucleotidase dephosphorylates the mononucleotides. Alternatively it might also be suggested that dihydro-cozymase is split at position (2) forming adenosin-diphosphoric acid, which is dephosphorylated by adenylpyrophosphatase present in the enzyme preparation. In either of these cases it seems probable that dephosphorylation of dihydro-cozymase, on account of its dibasic character, is facilitated more than dephosphorylation of monobasic cozymase.

No definite statement can be made as to the implications of the present observation until further investigations have been carried out.

Nucleotidase was prepared from intestinal mucosa according to Klein[6] and was purified by isoelectric precipitation at *p*H 4·7. The precipitate was dissolved in alkaline water and dialysed overnight.

Cozymase free from adenylic acid was reduced with sodium hydrosulphite at *p*H 7·2–7·4, and the excess of hydrosulphite was removed by aeration. The resulting dihydro-cozymase was carefully maintained at *p*H 7·6–8·0. The amount of dihydro-cozymase was estimated spectrophotometrically.

The experiments were carried out *in vacuo*, the substrate being added after evacuation in order to prevent re-oxidation of dihydro-cozymase and the reaction was stopped by 4 per cent CCl_3COOH without letting air enter the reaction mixture before it was acidified. Veronal buffer at *p*H 7·6 has always been used in the reaction mixture. It has been found that the dephosphorylation of dihydro-cozymase was not due to sulphate present. The parallel experiments with cozymase and dihydro-cozymase were done with the same cozymase preparation under identical conditions. Under the same experimental conditions, dephosphorylation of adenylic acid is about four times as large as that of oxidized cozymase.

The following table shows typical results :

Reaction time (min.)	Purity of cozymase per cent	γ P/mgm. cozymase	γ P/mgm. dihydro-cozymase
30	100	18·75	34·0
30	100	31·25	50·0
15	90	16·12	35·64
15	90	17·12	26·14
30	90	25·75	44·68

Standardization of Gonad-stimulating Hormones

In view of a recent publication by Hamburger and Pedersen-Bjergaard[1] relating to methods of standardization of the gonad-stimulating hormones, the following observations made in these laboratories may be of interest.

I am in complete agreement with Hamburger and Pedersen-Bjergaard's contention that the corpus luteum method in mice and the vaginal smear method in rats are the most accurate available for standardization of the urinary gonad-stimulating hormone (Gonan, Physex, etc.). Formerly, it seemed to me more logical to use the corpus luteum method[2], since I was engaged on problems in which this phase of activity of the hormone was of particular interest. With the widening of the scope for such preparations to include even treatment of male gonadal dysfunction this argument disappears. I now standardize Gonan in terms of its ability to produce œstrus in 50 per cent of immature rats (40–50 gm. in groups of not less than ten), when given over a period of 2½ days. Smearing is begun 1½–2 days after the last injection, if the vagina is open. The ratio of this rat unit to the mouse unit (luteinizing) has been found to be about 1 : 12 ; this compares with a 1 : 15 ratio found by the Danish workers.

With regard to standardization of the hormone of pregnant mares' serum (Serogan, Antex), I am not in such complete agreement with these workers. In the first place, it is interesting to note that they consider the rat a more suitable animal than the mouse when the criterion of activity is increase of ovarian weight. They give the average weight of a pair of infantile mouse ovaries as 2·2 mgm. ; in these laboratories I find a figure of 1·7 mgm. for our stock and, although I work with minimum groups of ten, I feel that dissection cannot be carried out with sufficient accuracy with organs of this size, and I invariably prefer to work with rats when adopting this criterion of activity.

It is, however, generally recognized that the gonad-stimulating hormone of the serum of pregnant mares is predominantly follicle-stimulating (or œstrus-producing), and it seems to me that the vaginal smear technique is therefore a logical one to use, apart from its (in my opinion) greater accuracy. With a view to the use of this method, I have therefore carried out a series of tests to determine the ratio of the mouse unit, that is, the amount required to double the weight of the ovaries in 4 days, to the rat unit, the definition of which is the same as described above in dealing with the gonad-stimulating hormone of human pregnancy urine. Groups of ten rats were used, and 1 rat unit was found to be about 1/10 mgm., the ratio R.U. : M.U. (as described above) being 1 : 2.

Finally, it will be observed that throughout this communication I have avoided using the term 'gonadotropic', which has been in common use for a considerable time. A recent letter from Dr. Parkes[3] has stimulated interest in the question of nomenclature, but I do not feel entirely satisfied with the suggestions made by him. I therefore prefer to adopt a system used for some years particularly by the American workers in this field, that is, to refer to the 'gonad-stimulating' hormones, until some general international agreement can be reached.

Failure of Anaphase Separation in Species Hybrids

In the meiosis of species hybrids we are accustomed to finding abnormalities which are due to structural differences, abnormalities such as failure of pairing of chromosomes. There are also instances in which the genotypic upset in the hybrid gives rise to an abnormal course of meiosis, usually likewise causing a failure of pairing, for example, *Drosophila pseudo-obscura*[1]. In a cross between two grasshopper species, *Chorthippus bicolor* Charp. and *Ch. biguttulus* L., which I have succeeded in obtaining experimentally as well as in Nature, I have found an example of genotypic abnormality which shows itself acutely for the first time during the anaphase separation of the normally paired chromosomes.

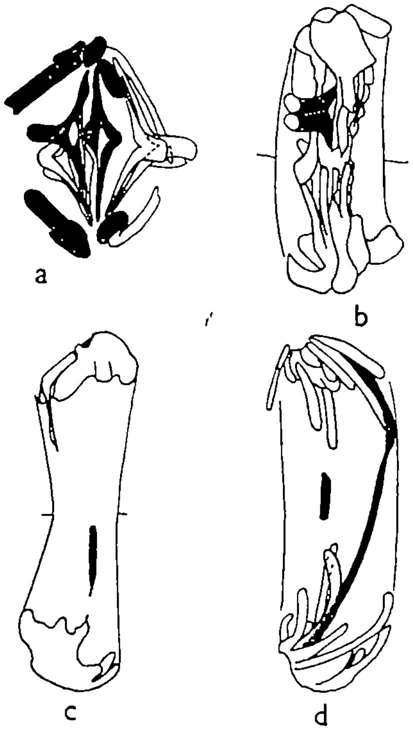

Fig. 1.

a, Meiotic anaphase in the hybrid. V-chromosomes shown in outline. *b*, Early telophase. Unseparated chromatids, one of which is broken, in black. *c*, Telophase. Piece of chromatid left behind. *d*, Gonial mitosis. Non-separation of two chromatids and piece of another chromosome left behind.

The chromosomes of *Ch. bicolor* have been described by Darlington[2] and those of *Ch. biguttulus* do not differ appreciably from them. In meiotic metaphase the bivalents are of the more contracted type found among the grasshoppers. But in the hybrid they are long and slender throughout, rendering the analysis of chiasmata very simple indeed. They are like the chromosomes of *Mecostethus*[3] and *Chrysochraon*[4], save for the variable arrangement of chiasmata which resembles that in the parent species. Owing to their slenderness, however, irregularities in the metaphase movements occur, showing that repulsions between the centromeres fail to be effective in causing movement when they are exceptionally far apart.

With this exception the beginning of anaphase is normal, but the further it proceeds the more obvious does it become that normal separation is being hampered (Fig. 1*a*). The parts between the centromeres and the nearest chiasma are often drawn out and not infrequently break. The chromatids beyond this chiasma, which should separate, stick to each other instead. In some cells they seem to yield eventually to the stress exerted by the spindle and separate. But very often they break (Fig. 1*b* and *c*), the pieces being included in the daughter cells or left behind. In a great many cases a single restitution nucleus is formed. The second division is still more irregular. Spermatid nuclei therefore vary in size and are often polyploid. In spite of all this a good deal of seemingly normal sperms are seen, but whether they are functional is not yet known.

During the examination of the hybrid cells the following explanation has suggested itself. In metaphase the chromatids are closely associated, nay optically indistinguishable in most cases. There is a specific attraction between them. This attraction is a condition for the tension between centromeres so often seen in metaphase of meiosis in bivalents with chiasmata close to the centromeres. As pointed out by Darlington[5], a necessary condition of anaphase separation is the lapsing of the specific attraction. That the chromatids become free by an autonomous lapse of attraction rather than by the pulling force of the centromere movement is evident from the observation that the chromatids (particularly of long chromosomes) in anaphase often let loose one another's distal parts without stretching of the already free proximal parts. It is true that on the other hand the chromatids not infrequently appear to be actively separated by the pull of the centromeres But if we assume that the lapse of attraction between the chromatids begins at the centromere and proceeds towards the ends at a rate that normally varies from one adjusted so as to keep pace with the centromere movement to a somewhat greater rate, such a variation in the appearance of the anaphase separation would be expected. All this, I think, holds good for mitosis as well as for meiosis, although perhaps often not so easily tested in the former case.

Assuming now that in certain circumstances the lapsing process is proceeding too slowly in relation to the centromere movement, or in other words that the distal parts remain in metaphase condition too long, the observed anaphase disturbances would appear. The bringing together in the hybrid of two different genotypes has, on this view, caused such an alteration of the synchronization of the anaphase events. That this may also happen in mitosis is shown by cases as in Fig. 1*d* and by the occurrence of incompletely separated meiotic prophase nuclei. It is obvious that in these hybrids the timing unbalance which shows itself in anaphase is correlated with the reduced or semi-mitotic contraction, both falling in the wide class of phenomena brought under a single aspect by Darlington's precocity theory.

It is interesting to note that occasionally a failure of the ends of chromosomes to separate has been observed in the parental species also. The process of anaphase is naturally affected by environmental variations like all genotypically controlled properties.

The behaviour of chromosomes in the meiosis of the hybrid is strikingly similar to that found by White[6] in *Mecostethus* 7¼ hours after X-ray treatment. In fact, his figures correspond exactly with those published here. Sax[7] has recently given an account of the varying agents (X-rays, temperature changes, chemicals, genes, ageing, etc.) which are known to affect nuclear division after division of the chromosomes. He points out that in most cases the irregularities seem to be similar and appear to be effected by disturbing the synchronization of nuclear and cytoplasmic activities. This disturbance may in some cases at least be of the kind inferred above.

To what extent permanent structural changes can be attributed to breakage in hampered anaphases remains yet to be studied.

Double Structure of Chromosomes

IN response to our demonstration[1] that the metaphase chromosomes of *Trillium* are composed of four strands twisted about each other in pairs, while the anaphase chromosomes contain two intertwined threads, Dr. Darlington[2] states that the appearance of two threads is an artefact induced by a fixative containing acetic acid, and due to "bubbles" arising in the chromatid. In confirmation of this, he publishes a photomicrograph of a cell in telophase which bears little resemblance to our figures.

The preparations photographed in our letter were fixed in strong Flemming, which contains acetic, but other preparations made at the same time and fixed in Benda without acetic, following treatment with vapour of ammonia, hydrochloric or nitric acid, gave the same result. This disposes of Dr. Darlington's argument that the double threads are due to the treatment, even if it were not untenable on other grounds. His "bubble" theory is a revival, under another name, of the conception which was current in 1911, and earlier, that anaphase and telophase chromosomes developed alveoli or vacuoles in passing into the resting condition. Also, according to definition, bubbles are composed of gas or vapour in a liquid medium, so that the use of the word is incorrect.

Dr. Darlington's question regarding the possibility of three threads in metaphase chromosomes is misleading, because a photograph in one plane of two intertwined threads twisted around two other intertwined threads will give, in places, a superficial appearance of alveoli side by side. But a photograph at this magnification cannot be taken in three dimensions.

Dr. Darlington has introduced the subject of chromomeres which has been dealt with in a paper now in course of publication. Suffice it to say that all recent critical observations on plant chromosomes show a continuous chromonema and not a discontinuous row of chromomeres.

Finally, it may be pointed out that the photomicrographs published in our previous letter[1], showing the doubleness of the chromosomes in *Trillium sessile*, were only the final proof concluding a long line of increasingly cogent evidence. That evidence is contained in innumerable papers from many laboratories, some of them so early as 1926, including a series of papers from this laboratory beginning in 1931. Dr. Darlington and his supporters face this mass of evidence with the assertion that the chromosomes must be single in anaphase and telophase because some of the X-ray experiments can be interpreted in this sense. White's work[3] on the X-irradiation of the first meiotic division in three species of insects casts doubt on this interpretation.

Effect on Organisms of Summer Drought in Caves

AMONG the most interesting of cavicolous invertebrates from Herzegowina is the Serpulid, *Marifugia cavatica* Abs. and Hrabě[1]. This remarkable worm, although belonging to a typical marine group, forms its calcareous tubes in great quantities over the walls and ceiling of the inland limestone cave known as Crnulja, in Popovopolje. The worm itself is known from this and a few neighbouring caves only; deserted tubes or their debris are more widely distributed, and may point to the existence of the worm in uninvestigated recesses of caves as far north as Istria. While visiting Popovopolje in August 1937 I found debris of the tubes in the much-explored Vjetrenica pećina, where Remy[2] has stated that it does not occur. I brought back some of the living worms from Crnulja to England, and am indebted to Mr. C. C. A. Monro for confirmation of the species.

During the winter the worms are immersed in fresh water; for the rest of the year they live retracted within their tubes, covered by only a thin film of water of condensation. The conditions then are so dry that Remy records the desiccation of a Plumatellid and its formation of statoblasts. In this connexion, I would record finding among the tubes of my *Marifugia* quantities of sponge gemmules, which have been identified by Dr. M. Burton as those of *Ephydatia mülleri* Lieberkühn. Above ground the gemmules of related Spongillidæ are stimulated to germinate by increase in temperature and give rise to young sponges in the spring. But, in the cave, conditions are reversed; the gemmules occur in summer and must give sponges in winter, the only time when the cave is flooded and sufficient water is available for active sponge life.

On returning to England, I made germination experiments with the cave gemmules, using gemmules of epigean *Spongilla lacustris* as a control. Of the latter, 50 per cent germinated in 10 days, and gave good sponges, with oscula and flagellated chambers. Of the cave species, however, only 2 per cent germinated in a period of 22 days; and the development here was quite abortive, neither oscula nor flagellated chambers appearing, although the germinating sponge material lived long enough and was extensive enough to have thus differentiated. It would seem, then, that in respect of gemmule germination, this cavicolous strain of *E. mülleri* reacts quite differently from the epigean *E. fluviatilis* L., which, according to Brien[3], behaves similarly to the control, *Spongilla lacustris*.

Stomatal Movement and Epidermal Water-Content

PROF. D. THODAY has suggested[1] that the remarkable stomatal behaviour of coffee may be explicable on a hypothesis involving variations in the water content of the epidermis as distinct from that of the leaf as a whole. As he says, a critical experiment would be the determination, in saturated air, of the relation between stomatal aperture and radiation. This has not been done.

However, the climatic range over which coffee is grown is wide: and I have determined its stomatal behaviour in semi-arid, cloudless, windy, unshaded and exposed conditions, and in moist, cloudy, shaded and almost wind free habitats. In the former, the relative humidity is very low, and the evaporating power of the air is consequently high. In the latter, the reverse is true, and relative humidity may remain very high throughout the day. Yet the relation between stomatal behaviour and incident radiation is similar in both habitats, and the stomata always close in strong light.

A sunfleck, illuminating one leaf on a coffee tree under dense shade and in a nearly saturated atmosphere, will cause rapid stomatal closure in that leaf, although physical evaporation and hence cuticular transpiration must be minimal.

It seems, therefore, unlikely that the peculiar stomatal behaviour of coffee, under these varied conditions, can be explained on the lines suggested.

---

[1] NATURE, 141, 164 (1938)

IN view of the information given by Mr. Nutman, I agree that my suggestion can scarcely apply. Mr. Nutman's observations appear to add a new type of response to the possible complexities of stomatal behaviour and make it still more evident that specific differences have to be considered.

D. THODAY.

Penetration of Ultra-Violet Rays through Chitin

ALTENBURG in 1928 found that the fluorescence of certain salts was only very slightly, if at all, affected when *Drosophila melanogaster* were interposed between the discharge tube of a Cooper Hewitt lamp and the salts at which the rays were directed. From this he concluded that the ultra-violet rays penetrated the chitin rather freely. His conclusion has been accepted by subsequent workers. Altenburg did not state, however, which salts were used, how many layers of flies there were, or how closely they were arranged. Besides, the shortest wave-lengths of visible light also cause fluorescence of salts.

In order to obtain more definite data, we planned experiments, using a Hanovia quartz mercury vapour lamp, to determine the limit of thickness of chitin that can still be penetrated effectively by the ultra-violet rays produced by this lamp. It was found that 60 minutes irradiation through a vitreosil plate 0·5 cm. in thickness had a striking effect on the wing development of rather aged pupæ. The distance was maintained at 11 inches. Of the imagines which emerged, approximately 60 per cent showed distinct wing modifications of great variety. Undoubtedly the hypodermal cells between the two chitinous layers of the immature wings were effected by these rays which must, therefore, have penetrated effectively through the chitin of the puparium and of the pupal wing. The control flies were treated in the same manner but the dishes, instead of being covered by a vitreosil plate, were covered by ordinary glass of the same thickness.

The control material showed no effect even after several hours of irradiation, while a dosage of more than 80 minutes proved very deleterious to the experimental material. A uniform dosage of 60 minutes irradiation was maintained for all pupæ treated in these experiments. Besides the wing abnormalities observed, the viability of the experimental material, that is, the pupæ covered by vitreosil plate, was reduced by about 30 per cent as compared with the controls

This positive effect of the ultra-violet rays on the wing development suggested a means of testing out the effective penetrability of chitin to ultra-violet rays. For this purpose the flying wings of the locust *Nomadacris septemfasciata* were used in preparing small screens 2 in. × 2 in. Sections of wings of this locust species showed that the thickness of the wing ranges from 4 μ to 10 μ. The wings were carefully pasted on to frames of fairly thick paper, care having been taken to keep the window portion clean of paste. In this manner screens of 1-, 2-, 3- and 4-wing thickness respectively were made, and irradiation experiments carried out as stated above.

A spectrographic analysis was then made of the wave-lengths which penetrated the prepared chitin screens distinctly. The results are shown in the following table:

Screen	Absorption in A	Percentage wing abnormalities
0·5 cm window glass	<3650	0
4 wings vitreosil	<3650	0
3 wings ,,	<3650	0
2 wings ,,	<3125	40
1 wing ,,	<2967	54
vitreosil	<2534 <2398 } (?)	60
quartz lens	<2225	62

The spectrum was mapped from 1900 A. to 4400 A. No lines were found below 2224·7 A. The range of the instrument is just outside the very intense mercury line 1849·6 A. As the absorption increases both with the increased thickness of the filters and with the decrease in wave-length, it is reasonable to suppose that light of wave-length 1849·6 A. will behave similarly to longer wave-lengths.

As a photo-densitometer was not available, quantitative expressions of absorption were not possible. It is hoped to rectify this in future experiments.

From these results it appears that our dosage was ineffective when the chitin layer was 3 wings (about 21 μ) thick or thicker; the wave-length 3125 A. was still biologically effective, but 3650 A. and longer wave-lengths were not.

We wish to thank Prof. G. H. Stanley, director of the Minerals Research Laboratory for the use of apparatus and Mr. L. W. Vermeulen for technical assistance.

An Effect of X-Radiation on the ξ Potential of Colloidal Graphite

IN their recent communication on the above subject[1], Prof. J. A. Crowther and H. Liebmann have discussed results obtained with graphite sols containing only a little ammonia.

A later paper[2] describes an effect, which, if genuine, must be of importance in connexion with the biological effects of X-radiation. They find that on adding a "small quantity of surface-active material" to a sol of the above type, the sensitivity of the sol to X-rays is completely destroyed.

If this is the case, it is unlikely that the striking effect of X-rays upon the surface-charge of a colloid discovered by these authors can occur during the irradiation of cancerous animal tissue, since most living cells contain surface-active substances.

[1] NATURE, 140, 28 (1937).

[2] Crowther, J. A., Liebmann, H., and Lane, T. B, *Phil Mag.*, 24, 654 (1937)

I AM very much aware of the fact that there is a very wide gulf between the simplicity of a graphite sol and the complexity of the intra-nuclear structures of living cells. If, from any unguarded expression in our paper, Mr. Kemp has been led to suppose that we imagined the gulf to have been crossed, he is wise to lodge a caveat. The curious effect of irradiation on the cataphoretic velocity observed by us in the case of colloidal graphite seems to be common to lyophobic sols, in general, and we have obtained it not only with amorphous carbon, both positive and negative, but also with gold, quartz, and ferric hydroxide.

The effect of irradiation on colloids of biological interest is now under investigation. Pending the results of these experiments, we should hesitate to draw general conclusions from the single observation to which Mr. Kemp directs attention, nor would we dogmatize as to possible applications to living cells. Too little is known about the chemistry of the cell and its nucleus. It is known, however, that biological changes are produced in the nucleus by doses of the order of magnitude which we are using in our experiments; and in view of the importance of the subject, any possible line of approach is worth exploring.

Structure of Heavy Elementary Particles

THE discovery of the heavy electron has recently led Bhabha[1] and Heitler to discuss in detail Yukawa's suggestion to account for nuclear forces by the assumption that a heavy particle is surrounded by a heavy electron of mass m during a fraction of time q.

It may be emphasized that this theory permits a very elementary treatment and allows us to obtain several consequences without extensive calculations. This is due to the fact that the emitted heavy electron, satisfying a wave equation of the type

$$\Box u - \varkappa_0^2 u = f(r) \,.\, \delta(r)\, exp\left(\frac{2\pi i}{h} Wt\right), \ \varkappa_0 = \frac{2\pi mc}{h}$$

is provided with an energy of the order of mass difference between proton and neutron, $W \sim \Delta Mc^2 \sim 10^6$ ev. (Taking the recoil into account: $W \sim \frac{1}{2}\, mc^2 \frac{m}{M} \pm \Delta M;\ m \gg \sqrt{2M\Delta M}$.) It behaves outside the proton (or neutron) like a free particle in the limiting relativistic case $W \ll mc^2;\ u \sim \exp(-\varkappa r)/r$.

The theory meets with difficulties similar to those of electrodynamics, but it is not unlikely that the problem of light nuclei falls within its domain of applicability. If this is the case, we are led to the following conclusions:

(1) The theory gives for the degree of dissociation the value

$$q = \frac{1}{1 + \sqrt{1 - (W/mc^2)^2}} \sim \tfrac{1}{2},$$

which means that proton-proton forces are only slightly smaller than proton-neutron forces.

(2) The magneton of the dissociating heavy electron becomes

$$\mu = \frac{h}{2\pi} \cdot \frac{ec}{W},$$

of the order of one ordinary Bohr magneton. Thus, only a small percentage of the dissociation can be directed by the spin of the heavy particle.

A detailed account of these considerations will be given in the *Physical Review*.

Methods of Estimating Mental Factors

IN a recent letter[1], Prof. G. H. Thomson has deduced an interesting relation between the equations which he and I have respectively proposed for estimating mental factors. It seems worth noting that this relation depends on a simple connexion between our estimates that previously I had not realized. Let the test scores for any one person depend on his or her group and specific factors, f_0 and f_1, according to the (vector) equation:

$$z = Mf = M_0 f_0 + M_1 f_1.$$

From the identity $K = J(1 - K)$, where $J \equiv M'_0 M_1^{-2} M_0$, $K \equiv M'_0 R^{-1} M_0$, $R \equiv MM' = M_0 M'_0 + M_1^2$, it is easy to establish the reversible relation between our respective estimates for f_0,

$$\hat{f}_0 = K\check{f}_0, \ \ \check{f}_0 = K^{-1}\hat{f}_0.$$

Thus *as a* (*vector*) *statistic* one estimate is equivalent to the other. Their different interpretation and properties might conveniently be summarized here by the formulæ:

$$E\{\hat{f}_0\} = E\{f_0\} = 0,\ E\{(\hat{f}_0 - f_0)(\hat{f}_0 - f_0)'\} = 1 - K;$$

$$E_1\{\check{f}_0\} = f_0,\ E_1\{(\check{f}_0 - f_0)(\check{f}_0 - f_0)'\} = J^{-1} = K^{-1}(1 - K),$$

where E denotes averaging over all persons, E_1 over all possible sets of tests (comparable with the given set in regard to the amount of information on the group factors f_0).

To anticipate obvious criticism, it should be remembered that these formulæ are at present somewhat theoretical, owing to the necessity of *postulating* the initial equation $z = Mf$; but, as I have mentioned before, more empirical methods of statistical analysis are always available which may ultimately help to justify and establish such postulated equations.

"Foundations of Terrestrial Life"

IN the brief account in NATURE[1] (Dec. 25, 1937) of a lecture by Sir Frederick Keeble on "Foundations of Terrestrial Life: The Soil and the Green Plant", the conclusion to which he had come is stated thus: "This hypothesis is that the health and strength of people and their evolution, and the permanence of human societies depend on the soil and the green plant." This recognition of the fundamental importance of the green plant suggests a reference to another but very ancient résumé of science contained in the much-discussed first chapter of Genesis (verse 30). "And to every beast of the earth and to every fowl of the heavens and to every creeping-one upon the earth in which is the soul of life, I have given every greenness of herb for food." (President Harper's translation.) The customary translation is "every green herb"; but the Hebrew words are far more emphatic than the English translation; they read: "every greenness of green herb". The Hebrew word for "green herb" is one of the widest significance, and seems, according to Gesenius, to include every herb that has food value both for man and beast.

It is interesting to observe that the earliest and the latest pronouncements of science on this point are in perfect accord.

Points from Foregoing Letters

A CURVE showing the average number of insects at various heights up to 2,000 ft., and diagrams indicating the comparative distribution of the nine more important families of insects, are submitted by Prof. A. C. Hardy and P. S. Milne. High temperature and low humidity were found to favour the aerial drift of insects. The insects were caught in nets 3 ft. in diameter, carried into the air by kites. The authors point out that wind-borne insects contribute not only to the spread of insect pests but also may possibly be carriers of foot-and-mouth disease.

Sir Joseph Larmor considers that if mountain ranges rest on a viscous foundation of *denser* material then, as the mountains accumulate locally, they would gradually sink down. The roots of the mountain would thus penetrate into the denser viscous material to an extent exceeding the height of the mountain, in order to compensate for the extra column aloft, very much like a submerged iceberg.

A description of the methods used in the preparation of the soluble amino-acid oxidizing enzyme of Krebs (from pig's kidney) and of its coenzyme (from horse-heart muscle) is given by Dr. F. B. Straub. The activity of the coenzyme is found to be proportional to its flavine content, and the author considers that flavine may be part of the active compound.

Nucleotidase (an enzyme which hydrolyses phosphoric esters) splits off the phosphate group from the molecule of cozymase (a coenzyme assisting the oxidation of carbohydrate), according to N. B. Das and Prof. H. v. Euler. The dephosphorylation takes place more slowly than in the case of the adenylic and inosinic acids. Dihydrocozymase also is dephosphorylated about twice as fast as cozymase, and this is attributed by the authors to the dibasic character of the former.

For the determination of the biological activity of urinary gonad-stimulating hormones (Gonan, Physex, etc.), P. G. Marshall prefers the vaginal-smear method in rats to the corpus luteum method in mice. Also in the case of the standardization of the hormone of pregnant mares' serum (Serogan, Antex) the author considers the vaginal-smear technique in rats preferable to the determination of the increase of ovary weight in mice, and gives the ratio of the mouse unit (amount necessary to double the weight of ovaries in four days) to the rat unit (amount needed to produce œstrus in 2½ days in 60 per cent of the immature rats).

In a grasshopper hybrid, studied by H. Klingstedt, owing to a failure in the separation of chromatids at anaphase, the chromatids often break or the separation of nuclei may be prevented. This abnormality is ascribed to a maintenance of metaphase attraction beyond its normal limit.

Prof. R. R. Gates and S. V. Mensinkai state that the double structure of chromosomes at metaphase was observed in preparations fixed with various reagents, and this excludes Dr. Darlington's objection, that the double-thread appearance is due to the treatment employed. The authors point out that much other evidence favours their view, and cast doubt on the X-ray experiments which have led Dr. Darlington to the opinion that chromosomes must be single in the anaphase and telophase stages.

R. S. Hawes describes the behaviour of the serpulid worm *Marifugia cavatica* in the inland limestone caves of Herzegowina which are flooded in winter and dry in summer. In the calcareous tubes of these worms he has found gemmules of the sponge *Ephydatia mülleri*. Only 2 per cent of these gemmules of the cave-dwelling species germinated under experimental conditions which were suitable for the development of the surface species *Spongilla lacustris* (which conditions had also been found to be suitable for the nearly related surface species *E. fluviatilis*).

Experiments carried out by Dr. G. Eloff and V. L. Bosazza show that chitin of approximately 0·02 mm. in thickness absorbed wave-lengths less than 3650 A. The biological effects are in keeping with the physical data. A Hanovia quartz mercury vapour lamp was used.

Research Items

Nayadis of Malabar

Mr. A. Aiyappan, in introducing his study of the social and physical anthropology of the Nayadis, a beggar caste of Malabar (*Bull. Madras Govt. Museum, N.S. Gen. Sec.*, 2, 4; 1937), points out that the centrifugal aspect of caste has diverted attention from the function of caste in the caste *milieu*. The Nayadis are the lowest known caste in India, polluting even the Pariah by their approach. When begging for alms in the stentorian voice, which is their most noticeable characteristic, they must stand yards away from the road. Their poverty and degradation constitute them a serious problem, which for long has engaged the attention of missionaries, administrators and social reformers. The origin of the Nayadis is obscure. A persistent tradition derives them from the Namputiri Brahmins, the highest grade in the Malabar social hierarchy, from which their forbears are said to have been ejected as 'unclean'. Sanctity is added to the repute of the caste by this tradition of origin. As beggars the Nayadis do not need to excite the compassion of the charitable as do those who have fallen on evil days. Their alms arise from the religious faith of the donors. They receive gifts on regular occasions—regular days of the week, and special occasions, such as the twelfth day of the waxing and the waning moon, and death-gifts. It is as much a sin to omit to give to them as to the Brahmins. Physically, the Nayadis stand midway between the hill jungle tribes and the castes of the plains; and in some there are distinctly Veddoid characteristics. The head is dolichocephalic and high. The estimated capacity shows that they belong to the microcephalic group. Their stature equals that of the lower castes, but is distinctly below that of the Namputiri Brahmins and Nayars. They are more platyrrhine than the lower castes, but less so than the Paniyans of the Wynad Hills.

The Zoology of Iceland

Under this title a work in five volumes is in preparation. A few parts are now published (Copenhagen and Reykjavik: Levin and Munksgaard, 1937) and include two by K. Stephensen: Marine Isopoda and Tanaidacea (vol. 3, Pt. 27) and Pycnogonida (vol. 3, Pt. 58). The Isopoda and Tanaidacea in the waters around Iceland (including the Faroes and Greenland) have been dealt with already by H. J. Hansen (Danish Ingolf Expedition 1913, 1916). Saemundsson (1937) has recorded the Icelandic Isopods from the Reykjavík Museum, and Stephensen himself (1929) has given a list of the species from Iceland in depths from 200 (300) metres. In the present work, the Isopods from 0–300 metres (the limits of the shelf) number 42 species and the Tanaidacea 9. *Aega tridens* alone is noted from Iceland for the first time. As the author points out, the comparatively small number of species is no doubt partly, but not exclusively, due to the somewhat isolated site of the island and is thus more apparent than real. The difference between Norway and Iceland is most marked in the very small forms, which have been thoroughly investigated in Norway, whilst the large easily noticed species occur nearly equally in both regions. Most of the Isopods and Tanaidacea found around Iceland are widely distributed in the northern part of the Atlantic with adjacent arctic waters. The main interest is connected with the fairly numerous species which are East Atlantic lusitanic-boreal, distributed in the north-eastern part of the Atlantic from the Mediterranean or south-west Europe northwards to Norway, the Faroes and Iceland, but found in Iceland only along the southern and western coasts. The Pycnogonida have not been hitherto so thoroughly investigated. Nineteen species are recorded, down to a depth of 300 metres, four of these for the first time. They are mainly widely distributed in the littoral and sub-littoral zones in the northernmost part of the Atlantic with adjacent arctic waters, with a few representing more special areas of distribution.

Mineral Deficiency affecting Farm Animals

The extent and influence of mineral deficiency on the growth and reproduction of farm animals have been investigated in Canadian agricultural research centres, as well as elsewhere, and are of special interest as part of the general study of the function of minerals in the thrift of domestic stock. As an aid to the investigation, the National Research Council of Canada has published a bibliography, compiled by Muriel E. Whalley, of papers dealing with mineral deficiencies as affecting the growth and reproduction of farm animals (Ottawa, 1937). The list contains 987 numbered entries arranged in alphabetical order according to authors, and covers the literature to the end of 1936. Cross references to the principal subjects mentioned in the titles have been included to assist the reader in gaining some idea of the scope and nature of the reference listed. Under each subject there is a numerical list of relevant references. The bibliography occupies 89 pages of duplicated typescript matter. The Council announces that a single copy of the bibliography will be sent free to anyone engaged in, or with special interest in, this field of research, on application to the Division of Research Information, National Research Council, Ottawa, Canada.

Larval Crustacea from the Red Sea

In his series of papers on Decapod larvæ, Dr. R. Gurney has contributed largely to our knowledge. A recent work ("Notes on some Decapod and Stomatopod Crustacea from the Red Sea" (3–5), *Proc. Zool. Soc. London*, Series B, 1937) deals in addition with certain Stomatopod larvæ. The natural position of the Stomatopoda is always a controversial point and the author's remarks on the larvæ are suggestive, showing that in many ways they are nearer to the Euphausiacea than to the Decapoda proper. He is of the opinion, and rightly so, that the difference between the *Lysiosquilla* type (Antizoea) and the *Squilla* type (Pseudozoea) is fundamentally important, showing as it does a different kind of locomotion, on one hand by the thoracic appendages and on the other by the abdominal. He was fortunate in obtaining eggs of *Gonodactylus glabrous* and the first and second larvæ from them as well as several stages from the plankton, making an almost complete series. *Lysiosquilla* larvæ (almost certainly the first stage), also described, are interesting in being intermediate between the Antizoea and Pseudozoea type, having the head and thorax of an Antizoea but with well-developed pleopods. *Callianassa* larvæ are discussed. Here there is always much that is difficult owing to the lack of definite identification. Two types exist, one (of which *C. subterranea* is an example) being found in a number of widely separated species, the other, less known, being closely related to that of Axius. The larvæ of a species of *Chlorotocella*, regarded as a Pandalid by Balss, is unusual in having the legs exceptionally backward in development and in having no exopods on the last four pairs of legs.

Elm Disease in Great Britain

A BRIEF memorandum on the elm disease was issued by the Forestry Commission in 1934. This Leaflet No. 19 is now reprinted (1938). The elm disease was first discovered in Holland in 1919 and is therefore referred to as the Dutch elm disease (*Ophiostoma ulmi*). It has been noted in Great Britain since 1927 and is fairly widespread over England, but does not extend to the north of Alnwick and is not reported from Scotland. The disease is now common throughout western and northern Europe; also in the United States. Many trees have been killed by it in Belgium, France, Germany, Holland and Italy. The first sign of the disease is a discoloration and withering of the leaves in the crown or at the ends of the branches. This is usually followed by defoliation, dead shoots being characterized by a drooping of the twigs, particularly noticeable in the months of summer. The trouble about this disease and the chief remedy (felling the tree affected) is that the severity of attack and the rate of progress of the disease are very variable. Trees may be killed in a single year, or the dieback may be more gradual, and if left standing they may entirely recover. Trees of all ages may be attacked, but small plants in nurseries and elm hedges are less frequently attacked than older trees. It is said that elms which have been pollarded, or severly lopped, are especially liable to infection. It is also held that the disease is spread by the elm bark beetles, *Scolytus destructor* and *S. multistriatus*; but observers are not at present unanimous upon this point. As regards the present position in Great Britain, between 1927 and 1931 the disease increased steadily. In 1932 there was a definite check, since when the disease has made steady progress, especially rapid in Worcestershire, but even in the worst regions it is said that the proportion actually killed is small. Attacked trees, therefore, should not be felled unless they become unsightly or die.

Fungi of Cyprus

GREATER knowledge of the problems of fungus ecology is one of the surest foundations for economic plant pathology of the future. One of the first requisites is an exact taxonomy of the fungi which occur in regions of characteristic climate. Dr. R. M. Nattrass has ministered to this need by publishing "A First List of Cyprus Fungi" (pp. xvi + 87. Nicosia, Government of Cyprus, price 2*s*. net, 1937). Details of climate and characteristic husbandry are given, and most of the fungi recorded seem to be typical of the Mediterranean region. There appears to be, however, a distinct mycological link with India. Six new species are proposed. Several cosmopolitan parasitic fungi which are usually found in widely varying habitats are absent from Cyprus. *Nectria cinnabarina*, the coral-spot fungus, *Stereum purpureum*, the cause of silver-leaf in plums, *Ophiobolus graminis*, or 'take-all' of wheat, and the wart disease of potatoes, *Synchitrium endobioticum*, are examples. Fifteen plates delineate the characters of the new species and other uncommon fungi.

Assyrian Chemistry of the Seventh Century

DR. R. CAMPBELL THOMPSON delivered a lecture on March 16 to the Society for the Study of Alchemy and Early Chemistry on "Assyrian Chemistry of the Seventh Century B.C." The lecture showed that cuneiform records going back to the seventeenth century B.C. contain recipes for carrying out chemical processes, but the greater part of the abundant literary material is from the seventh century and is in the British Museum. The translation of these tablets by Dr. Thompson has made it possible to reconstruct with considerable probability the range of materials used by the ancient Assyrian chemists, and it is interesting to find that enamels and glasses coloured by metallic oxides and possibly gold were made by processes depending on the use of definite weights of materials. Elaborate lists of stones were drawn up and it seems as if these include scales of hardness similar to the modern Mohs' scale. Various salts were in use, and it is even possible that fuming sulphuric acid was obtained by distilling green vitriol. An account of the lecture will be published in *Ambix*, the journal of the Society.

The Photographic Image

R. W. Gurney and N. F. Mott (*Proc. Roy. Soc.*, A, 164, 151; 1938) have applied the quantum theory of solid photo-conductivity to the production of the photographic image. If an electron is introduced into the silver halide lattice it is able to jump from ion to ion through the crystal, its energy lying in a band of 'conduction levels'. Such electrons are liberated from the halogen ions by the action of light, and whenever they come in contact with a speck of metallic silver they are captured. The negatively charged silver specks then attract silver ions which have left their normal lattice positions as a result of heat motions. This explains the direct darkening of silver halides by light (print out effect). It is clear that the efficiency of the process will be reduced at low temperature, and this is in agreement with experiment. The formation of the developable 'latent' image is due to the production of a sub-microscopic silver speck on the surface of a halide grain. The well-known sensitizing effect of traces of sulphur may be due to the sulphide specks localizing the formation of silver specks at points on the surface of the grain where the developer can get at them. It is shown that the silver specks will not be able to grow unless a certain concentration of electrons is provided by the photo-electric action, and on this basis the relations between time of exposure, intensity of light and blackening may be explained. There is a short discussion of the reversal of the image by red light and of the sensitization of emulsions by dyes.

Quantitative Methods in Psychology

A MEETING of the Royal Society was held on March 24 to discuss the application of quantitative methods to certain problems in psychology. The discussion, which was on three different problems, was introduced by Dr. C. S. Myers, who pointed out that conscious experience can only be measured numerically in terms of the antecedent physical stimulus, the concomitant physiological activities, or the consequent changes in outward behaviour. If mathematical operations on psychological data are to be of psychological value, each step in such operations must be carefully studied so as to be assured that it is psychologically warranted and not merely of interest to the mathematician. The psychological whole being greater than the sum of its parts, and the nature of these parts being dependent on the whole, the limitations of psychological atomism and psychological mechanics must always be borne in mind. But even if factorial analysis, although mathematically possible, may have only a limited use in applied psychology, nevertheless occupational guidance and selection, as at present practised, are demonstrably of considerable value.

STATISTICAL METHODS

Prof. C. E. Spearman, who opened the first discussion, on recent developments of statistical method, described the development of factorial analysis as illustrated by his own work and that of Kelley, Thurstone and Holzinger. Prof. G. H. Thomson said that in his view vocational prediction entails the projection of a point, given by *n* oblique co-ordinate axes called 'tests', on to a vector representing the 'occupation', the direction cosines of which are known but which is not in the *n*-space of the tests. The use of factors, whether oblique or orthogonal, merely involves reference of that point to a new set of co-ordinate axes called 'factors', instead of to the original test-scores—a procedure which, he argued, cannot define the point any better and may, unless great care be taken, define it worse. The chief value of the factor theory probably lies in its serving as a spur to further investigations and hypotheses. His belief is that the comparatively low rank to which so many matrices of mental correlation coefficients can be reduced indicates that the human mind is comparatively undifferentiated, protean and plastic, rather than that it is composed of separate faculties.

Prof. C. Burt regarded the factors isolated by analysis as merely convenient descriptive concepts which may, or may not, have a psychological basis. They need have no 'real existence', but serve much the same purposes as the lines of latitude or longitude upon a terrestrial map. In statistics the important measurement is not that of the clue and its consequence, but the measurement of the probability connecting the two. He referred to the great value of R. A. Fisher's formulæ for small samples, before the discovery of which it was considered that statistical methods could not be applied to less than 50 or 100 cases, and consequently the more detailed studies of the individual tended to give place to vast collections of inaccurate data. He also alluded to the easy comprehension and to the great value of matrix algebra for analytical purposes in statistical psychology—a method rarely utilized in the textbooks of pure statistics ; and to certain close analogies between recent developments in factor psychology and those in quantum mechanics.

A discussion of this subject followed by Drs. H. B. Heywood, J. O. Irwin and W. Stephenson.

INDUSTRIAL ACCIDENTS AND SICKNESS

Prof. M. Greenwood introduced the next subject—industrial accidents and sickness. He described how his early work at the Ministry of Munitions in 1918, on the distribution of accidents among those exposed to the same risk of them, led to later investigations conducted with the object of arriving at a statistical expression of the true and popular view that some people are 'all thumbs'. He was followed by Dr. May Smith, who gave an account of investigations conducted by the Industrial Health Research Board into the comparative absenteeism through sickness of those employed in selling, office work and manufacture. She indicated how dependent absenteeism also is on age, sex, incentives and management.

Mr. Eric Farmer and Mr. E. G. Chambers contributed to the discussion of this subject by describing their work on tests for the 'accident-prone', which provide with fair accuracy a prediction of accident rate for different groups of workers, although they are not sufficiently reliable in the case of any individual worker.

INDUSTRIAL SELECTION

The last discussion, on psychological tests in industrial selection, was opened by a communication from Sir Frederick Marquis, who described the promising value of special tests for salesmanship introduced a year ago into Lewis's stores, but had found tests for general intelligence to be of no value. Mrs. Raphael pointed out that in another large stores the National Institute of Industrial Psychology had found no linear correlation between intelligence and retail salesmanship, too much intelligence being as undesirable a qualification as too little.

Wing Commander R. H. Stanbridge described an experiment on the selection of aircraft apprentices with the aid of psychological tests. He found tests of intelligence and mechanical aptitude to be correlated with the passing-out results and to be definitely serviceable. Dr. W. G. Hiscock described the use of selection tests devised by the National Institute of Industrial Psychology for the Grangemouth branch of the Dye-stuffs Group of Imperial Chemical Industries, Ltd. Since 1934 all applicants for employment in the works have been submitted to these tests, as well as to a special medical examination, and not a single chemical process-worker has been discharged on the ground of inefficiency. Dr. Millais Culpin gave an account of an interesting investigation into the relation between 'nervousness' and the satisfactory and continued work of telegraph operators.

Discovery of the Femur and the Humerus of *Sinanthropus Pekinensis*

By Prof. Franz Weidenreich

Cenozoic Research Laboratory, Peiping Union Medical College

THE FEMUR

AMONG the extensive material recovered from Locality 1 at Choukoutien during the excavations of 1936–37 and afterwards prepared in the Laboratory, Dr. W. C. Pei discovered two fragments of femora. The general appearance of these specimens led Pei to believe that they were of human origin and probably belonged to *Sinanthropus*. A careful study and comparison with human and anthropoid thigh-bones resulted in the conclusion that the femora undoubtedly belong to *Sinanthropus*.

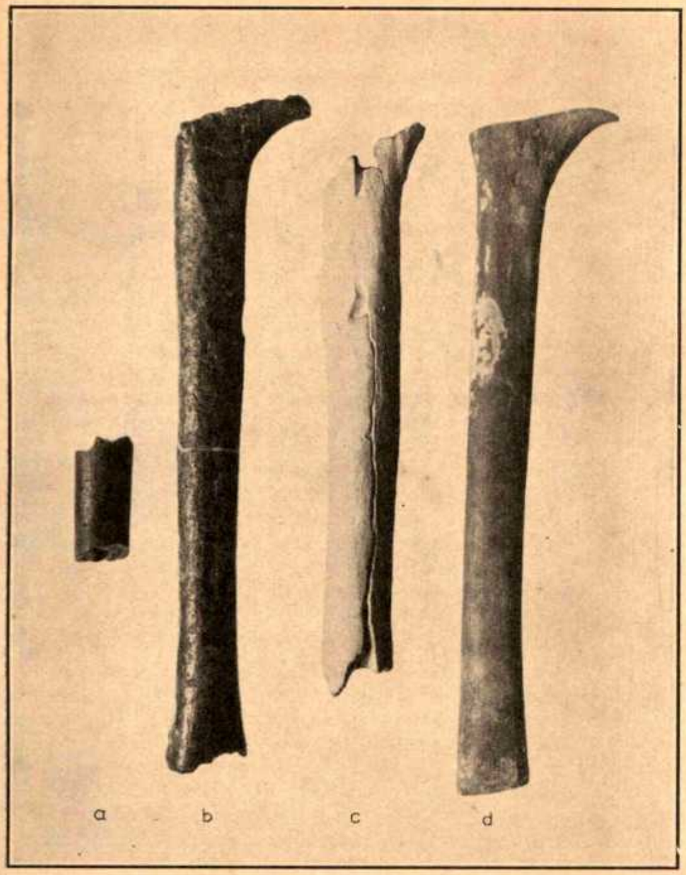

Fig. 1.

COMPARATIVE VIEW OF THE ANTERIOR SURFACE OF FEMORA: (*a*) *Sinanthropus* FEMUR *J*; (*b*) *Sinanthropus* FEMUR *M*; (*c*) THE FRAGMENT OF A FEMUR OF THE MAN OF WEIMAR-EHRINGSDORF (NEANDERTHAL GROUP) WHICH HAS NOT BEEN DESCRIBED (CAST); (*d*) FEMUR OF A FEMALE INDIVIDUAL OF RECENT MAN (MORAVIAN)—UPPER AND LOWER PARTS REMOVED TO CONFORM TO THE SIZE OF THE *Sinanthropus* FEMUR *M*. (×3/10.)

Femur fragment I was recovered from Level 23 in the western area of the cave, that is to say, Site *J*, from which we already have several fragments of an adult female skull described as Skull *J* in 1937, and four skull fragments of a very young child recently found among the prepared material. Femur fragment II comes from Level 26 of the western area of the cave, from which we have two fragments of one adult male and one adult female mandible as yet not described. Femur specimen I will be known as Femur *J* and specimen II as Femur *M*.

Femur *J* (Figs. 1 and 2, *a*) represent a portion of the middle of the shaft and measures 58 mm. The bone is completely fossilized and burnt, as is evident by the marked blackening of the entire anterior and medial surface and on the part where it was broken off. That we are actually dealing with a human femur is demonstrated by the form and size, but particularly by the existence of a rather distinct pilaster (Broca) which occupies the middle of the posterior surface and bears a well-developed linea aspera dividing into characteristic medial and lateral lips toward the end of the fragment.

Femur *M* (Figs. 1 and 2, *b*) embraces almost the entire diaphysis. Its length is 312 mm. At the upper end, the head and trochanters are broken off, whereas the entire inferior border of the neck is preserved. The lower end is likewise missing but the upper end of the suprapatellar fossa is still recognizable. This femur also is strongly fossilized. Certain parts of the surface are weathered but all the characteristic features are sufficiently preserved to permit a criterion. Like specimen *J*, this piece shows a distinct pilaster running along the middle of the posterior surface and bears a linea aspera consisting of two lips. Its relative completeness, however, makes it possible to determine the general form and the peculiarities of the shaft. Estimated on the basis of the length of the preserved portion of the femur, the total length may have been 400 mm.

The femur of *Sinanthropus* has, in common with that of recent man (Figs. 1 and 2, *d*), the general shape and the formation of a pilaster with a two-lipped linea aspera. In addition, there is a suprapatellar fossa, its lateral border being formed by a distinct ridge which gradually disappears towards the middle of the shaft. The trochanter tertius and the intertrochanteric line are missing. On the other hand, the femur differs from that of recent man by its stoutness—it seems that the distal end in particular was shorter and broader than in recent man in proportion to the length and breadth of the femur—and by the following specific features: (1) a very pronounced platymery of the entire length of the femur combined with the formation of a distinct pilaster (Figs. 2 *b*; 3 *a*-*c*); (2) a very faint curvature the greatest height of which is located near the lower end of the diaphysis (Fig. 2 *b*); (3) the transversal diameter of the shaft is narrowest near the lower end and gradually increases toward the upper portion (Fig. 1 *b*); (4) there is a distinct but only faintly developed crista lateralis superior (Fig. 1 *b*); (5) sections show that the cavity is narrow with rather thick walls, especially the anterior and posterior ones (Fig. 3 *d*).

Femora of the Neanderthal group (Figs. 1 and 2, *c*) differ from the femur of *Sinanthropus* by their greater stoutness, the transversal diameter being narrowest in the middle of the shaft, by a much more pronounced curvature the greatest height of which is also located near the middle of the shaft, and finally by the development of a very strong crista lateralis superior (Fig. 1 *c*). To what extent these differences are due to sexual characters is difficult to define. It seems that all the femora available of the Neanderthal group belong to male individuals, whereas I consider the two femora of *Sinanthropus* as belonging to females on account of the smallness of the two main diameters of the shaft (Table 1, Figs. 1 *b* and 2 *b*). In addition, femur *M* comes from the same site as a fragment of a lower jaw (*M* I) with two teeth which had been attributed to a female individual.

When compared with the femora of the great apes, those of *Sinanthropus* represent quite a different type. The general character of the shaft does not conform to any of them. It is of special interest that the *Sinanthropus* shaft also fails to show any similarity to that of a gibbon, the shaft of the latter being slender as in recent man, with the narrowest part at its middle. It may be deduced from this fact that the frequently stated similarity between femora of gibbon and recent man is of secondary nature and not in the least a fundamental one.

These discoveries of the *Sinanthropus* femora may also serve to shed some new light upon the problem connected with the *Pithecanthropus* femur. Its discoverer, E. Dubois, attributed it as belonging to the same individual or type as that represented by the *Pithecanthropus* skull cap. The fact that the femur closely resembled one of recent man not only in respect to its general character but also in certain other details was at no time held in doubt and distinctly admitted by Dubois. According to him, one of the most essential differences between the femur of *Pithecanthropus* and that of recent man should be a pronounced convexity of the upper portion of the popliteal surface of the former.

Femur *M* of *Sinanthropus* differs from the *Pithecanthropus* femur by exactly those features by which it differs also from that of recent man. But with reference to the popliteal surface it shows the same slight convexity as is common in recent man, the platymeric index of this region being 76·4 in *Sinanthropus* against 100·0 in *Pithecanthropus* (Table 2). The convexity of the popliteal surface of the *Pithecanthropus* femur, therefore, cannot be considered a primitive character.

It results from these facts that the *Pithecanthropus* femur is either one of recent man and with no close relationship to the skull cap, or it really belongs to the latter and thereby testifies that *Pithecanthropus* represents a much more advanced hominid type than *Sinanthropus*. I consider the first alternative to be the correct one. As proved by the skulls, both *Sinanthropus* and *Pithecanthropus* exhibit in general approximately the same degree of primitiveness. On the other hand, the femur of *Sinanthropus* reveals that the *Pithecanthropus* femur, besides other differences, is much too long and too strong for so small a skull.

In a lecture delivered in December 1937 before the Peking Society of Natural History, I pointed out that the character of the then available specimens of extremity bones of *Sinanthropus*, particularly the collar bone, indicated a more man-like appearance than the skulls and more especially the teeth. On the basis of this, together with the cultural remains, I came to the conclusion that *Sinanthropus* must have already adopted a completely upright posture and that the approach of the extremity bones to those of man preceded that of skull and teeth. Such a conception has now been confirmed by the discovery of the femur of *Sinanthropus* and thus leaves no room for doubt that the posture of *Sinanthropus* was erect. Since the total length of the femur (female) may have approximated 400 mm., the stature of the woman can be estimated to have been about 5 feet (152 cm.), a height which would correspond

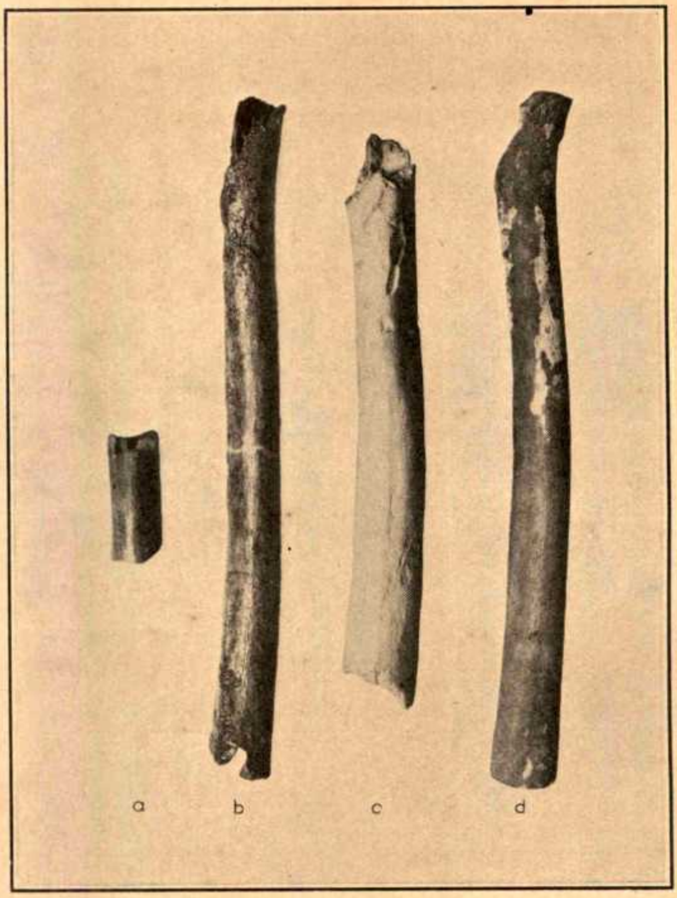

Fig. 2.

THE SAME FEMORA AS IN FIG. 1 VIEWED FROM THE LATERAL SIDE. (× 3/10.)

to 5 ft. 4½ in. for male individuals. With such a height, *Sinanthropus* ranges within the group composed of medium-sized people of to-day. At any rate, it is certain that *Sinanthropus* was not a pygmy.

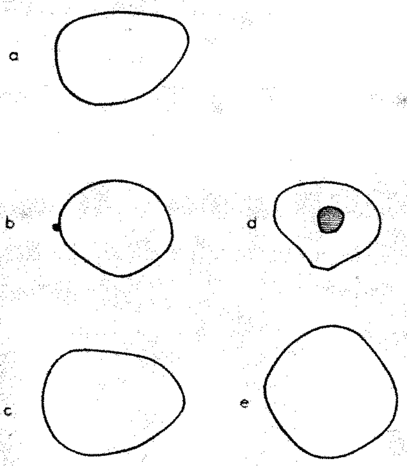

Fig. 3.

SECTIONS OF *Sinanthropus* AND *Pithecanthropus* FEMORA: (*a*) *Sinanthropus* FEMUR *M*, IMMEDIATELY BELOW THE LESSER TROCHANTER; (*b*) THE SAME FEMUR, SECTION OF THE MIDDLE OF THE SHAFT; (*c*) THE SAME FEMUR, SECTION OF UPPER PART OF THE SUPRAPATELLAR FOSSA; (*d*) *Sinanthropus* FEMUR *J*, SECTION OF THE MIDDLE OF THE SHAFT WITH THE CAVITY MARKED; (*e*) *Pithecanthropus*, SECTION OF THE UPPER PART OF THE SUPRAPATELLAR FOSSA IN CORRESPONDENCE TO SECTION *c* OF *Sinanthropus* FEMUR *M*. (× ½.)

The three facts, namely, that the two femora were found as isolated pieces without any other human bones; furthermore, that they represent only more or less complete specimens, and finally that the fragment of femur *J* was burnt, point in the same direction as the finds of skull and jaws. All the *Sinanthropus* bones recovered from Locality 1 of Choukoutien had received the same treatment as the game which *Sinanthropus* hunted. This hominid, therefore, was a cannibal. *February 10.*

TABLE 1.

PRINCIPAL MEASUREMENTS OF FEMORA (IN MM.).

	Sinanthropus M ♀	*Sinanthropus J* ♀	*Pithecanthropus* ♂
1. Transversal diameter			
(*a*) upper end	34·3	—	34·6 ?
(*b*) middle	29·0	27·3	28·0
(*c*) upper popliteal region	36·0	—	34·3
2. Sagittal diameter			
(*a*) upper end	22·1	—	31·0
(*b*) middle	24·1	22·6	29·0
(*c*) upper popliteal region	27·5	—	34·3
3. Circumference (middle of shaft)	88·0	77·0	89·0

THE HUMERUS

Shortly after the discovery of two fragments of the femur of *Sinanthropus pekinensis*, Dr. W. C. Pei recognized, among the material of Locality 1 of Choukoutien now in preparation in the Laboratory, a fragment of a humerus. This fragment comes from the same level (23) as the femur fragment *J*, but was found about 13 m. away from the latter.

The fragment is strongly fossilized and represents the greater part of a left diaphysis the total length of which is 187 mm. Both end parts are missing and apparently broken away previous to the process of fossilization. There is no doubt that the humerus belongs to *Sinanthropus*, its general appearance being rather similar to that of Neanderthal or recent man. But at the same time conspicuous differences are evident, namely, the diaphysis is very slender, the smallest circumference being only 60 mm. and the

7. Index of the robustness of the wall									
(*a*) ant. wall	37·1	30·1	—	—	♀ 23·9				
(*b*) post. wall	37·1	40·7			33·4				
(*c*) lat. wall	39·4	39·7			34·2				
(*d*) med. wall	30·8	36·3			24·7				
8. Collar angle	circa 110°	—	123°	115–120°	121–133°	115°	120°	130°	130°

circumference immediately below the surgical neck only 71 mm. The markings of muscle insertion, however, are surprisingly well pronounced, especially those of the deltoid and pectoralis major. The tuberositas deltoidea continues in a ridge-like projecting crest, the total length of which is 15 mm. The crista tuberculi majoris is likewise strongly developed, and there is also a well-circumscribed tuberositas corresponding to the attachment for the m. teres major. The sulcus radialis is also rather distinct, indicating a well-developed torsion of the humerus. In addition, the borders represent sharply demarcated edges, so that a cross-section of the upper part shows an almost quadrangular outline, while one of the lower parts beyond the end of the tuberositas deltoidea has the form of a real triangle. These features combined give the humerus of *Sinanthropus* a specific character.

In view of the deficiency of the fragment, it is not possible to determine with any degree of certainty the original length of the humerus. On the basis of the form and length of the fragment, however, the total length may be estimated to have been at least 310 mm. Despite the strong development of the muscle markings and the edge-like character of the borders, I consider the humerus as belonging to a female individual on account of its extraordinary slenderness.

As is evident from this brief description, the humerus of *Sinanthropus* does not show any special similarity to the humeri of great apes. It is specifically human in its entire appearance. The strong development of the muscle markings, especially those of the deltoid, pectoralis major and teres major and the edge-like character of the borders indicate that the upper limb was used in the same manner as in recent man, that is to say, it was already completely freed from locomotion. So far as is possible to deduce from the fragments of femur and humerus, their proportion in length may have been the same in principle as in recent man.

The view I have recently put forward that the skeleton of *Sinanthropus* approached that of man much closer than the brain case and the teeth do, receives additional support by the discovery of the humerus.

February 17.

Science News a Century Ago

Medical Missions

The March issue of 1838 of the *Gentleman's Magazine* contains the following information: "The first evening meeting of the Royal College of Physicians was held in Trafalgar Square on February 5, and a more crowded audience of members and visitors has, perhaps, never occurred. Amongst the latter were his Royal Highness, the Duke of Cambridge, the Duke of Wellington, the Archbishop of Canterbury, the Bishop of London, the Chief Justice of the Common Pleas, Sir Lancelot Shadwell, Sir Robert Peel, etc., etc. The President, Sir Henry Halford, read a paper recommending in eloquent terms the union of medical with theological knowledge in the attainments of missionaries to the eastern nations, and pointing out the great advantages which would result from such a connexion. He observed that great progress had been made in China and the other Asiatic countries in the healing art by the energy of the missionaries, and that vaccination and other European improvements in medicine had been introduced by their instrumentality. Sir Henry also took a view of the state of national physiology and pathology as understood in China, and pointed out the absurdities of the system of the natives."

English Physicians in France

The issue of the *Lancet* of March 31, 1838, contains the following information: "The affair of the English physicians in France (prosecution for unauthorised practice at Boulogne) has terminated in the condemnation of Drs. Carter, Scott, Shuter, Allatt and Galbraith to the payment of a trifling sum, which, however, is equivalent to an interdiction from practising medicine in France. This decree has naturally been very unsatisfactory to the British residents at Boulogne who have forwarded a petition to the King of the French on the subject; but their application will probably be of no avail, for we have been informed that, at a recent meeting of the Senate of the University of France, not less than ten demands from foreign physicians for permission to practise have met with a decided refusal. A leading French journal suggests that physicians furnished with diplomas from any foreign university or chartered body should be immediately admitted to the final examination (at a reduced fee) before the Faculty of Medicine of Paris. This appears to be the only feasible way of compromising the matter."

Faraday's Researches in Electricity

On April 5, 1838, at a meeting of the Royal Society, the reading of Faraday's Thirteenth Series of "Experimental Researches in Electricity" was resumed and concluded. "The author, in this paper," said the *Athenæum*, "pursues the inquiry into the differences observable in the luminous phenomena of the electric discharge, according as they proceed from bodies in the positive or the negative states, with a view to discover the cause of those differences. For the convenience of description, he employs the term *inductric* to designate those bodies from which the induction originates, and *inducteous* to denote those whose electric state is disturbed by this inductive action. . . . He also directed his attention to the peculiar luminous phenomena attending the disruptive electrical discharge, which he terms a glow, . . . and the *convective*, or carrying discharge—namely that effected by the translation of charged particles from one place to another. He lastly considered electric currents, not only in their effects on the bodies they traverse, but also in their collateral influences, as producing inductive and magnetical phenomena. He announced his intention shortly to give further views he entertains concerning the nature of electric forces and electric excitation in connexion with the theory he had advanced."

The Ant-tree of Guiana

At a meeting of the Botanical Society on April 6, 1838, the Secretary read a paper from R. H. Schomburgk (still in British Guiana) on the *Triplaris Americana*, the ant-tree of Guiana. The trunk, the letter said, is slender, grows up straight, and its erect branches form a pyramid. It is unisexual; and the flowers of both sexes are insignificant: those of the male last only for a few days, when they dry up; this is likewise the case with the petals of the female. The segments of the calix, however, continue to grow from green to white and vermilion, and become so attenuated that the branched nerves are easily perceptible. The tree presents a most elegant appearance. The incautious botanist who, allured by the deceptive appearance, should approach to pluck the blossoms, would rue his attempt. The trunk and branches are hollow like those of the trumpet tree (*Cecropia*) and provided between space and space with partitions, which answer to the position of the leaves on the outside. These hollows are inhabited by a light brownish ant, about two- to three-tenths of an inch long, which inflict the most painful bites, causing swelling and itching for several days. If they find themselves captured, they attack and kill one another like scorpions. The Aramah Indians call the tree 'Jacuna' and the ant 'Jacuna Sae'.

The British Association and Steam Navigation

At the Liverpool meeting of the British Association in 1837, a grant was placed at the disposal of a committee to investigate the speed and fuel consumption of steam vessels, and the Peninsula Steam Navigation Company had liberally offered to cooperate with the committee in trials to be made in their ship the *Tagus*. With the view of making the necessary records, Dr. Lardner had made an apparatus which would enable the steam engine to make a journal of its own proceedings.

According to the April 1838 number of *The Civil Engineer and Architect's Journal*, his apparatus was intended to record the pressure of steam in the boiler, and in the engine, the vacuum in the condenser, the revolutions of the paddlewheel, the amount of water in the boiler and its density. The records were made by coloured pencils on a paper driven by clockwork, the apparatus being enclosed in a case 3½ ft. high and 3 ft. in diameter which was to be locked at the beginning of a voyage and was not to be opened until the ship returned to port. The coal consumed was to be ascertained from the amount on board at the beginning and the end of the voyage.

University Events

Cambridge.—J. A. G. de Courcy has been appointed superintendent of the Engineering Workshops.

The Managers of the Frank Edward Elmore Fund have appointed Dr. J. C. Sinclair to a studentship.

J. R. Robinson, of Emmanuel College, has been awarded the Allen scholarship.

Leeds.—C. L. Bird has been appointed lecturer in dyeing.

Liverpool.—Dr. Rupert Montgomery Gordon, director of the Sir Alfred Lewis Jones Research Laboratory, Freetown, Sierra Leone, has been appointed to the Dutton Memorial chair of entomology in succession to Prof. W. S. Patton, who resigned in December last.

London.—Dr. F. R. Winton has been appointed, as from October 1, 1938, to the University chair of pharmacology tenable at University College. Since 1933 he has been reader in physiology in the University of Cambridge.

Dr. R. V. Christie has been appointed as from April 1 to the University chair of medicine tenable at St. Bartholomew's Hospital Medical College. Since 1935 he has been assistant director of the Medical Unit and assistant physician at the London Hospital.

Societies and Academies

Paris

Academy of Sciences, January 31 (*C.R.*, 206, 289–384).

Ernest Esclangon: Clocks indicating simultaneously mean solar time and sidereal time. It is possible to have a master clock, showing mean solar time, connected by a train of wheels to another clock showing sidereal time. The choice of the number of teeth on the connecting wheel work is worked out and a number of examples given showing the gear train and the corresponding error in seconds after 100 years starting with 1938.

Gabriel Bertrand and Georges Brooks: The composition of fibres, shells and other lignified plant tissues. Studies from the point of view of the chemical or biological utilization of these plant products.

Dimitri Riabouchinsky: Comparison of the method of the variables $(\varphi, \psi_1, \psi_2, t)$ with those of the variables of Euler and of Lagrange.

Marcel Godchot and Mlle. Germaine Cauquil: The molecular transpositions obtained in the dehydration of the 1-methyl-3-cyclohexylisopropyl pinacones.

Edouard Chatton: The plurality of the species of *Orchitosoma* and on their nature: the spermatogenetic evolution of Metazoa taking place in the parasite state in the ovary of Copepods.

Jules Dubourdieu: Remarks relating to the theory of assurance accidents.

Wolfgang Dœblin: First elements of a systematic study of the ensemble of powers of a law of probability.

Karl Menger: A simplified axiomatic of the algebra of projective geometry.

Gustave Choquet: Study of certain networks of routes.

André Lichnerowicz: Regular space-time exteriors.

Louis Sackmann: The comparative study of the *portance* of a wing of an aeroplane and of the régime of flow on the extrados.

Jean Mandel: The equilibria through plane parallel sections of plastic media at the limit of flow, and, in particular, of earth and of the ductile metals.

Jean Louis Destouches: Centre of gravity and relations of uncertainty.

Mlle. Natalie Rein: A form of differential equations of the limited elliptical problem.

André Danjon: The determination of the elements of the orbits of visual double stars.

Joseph Mikulaš Mohr: The dependence of the observed radial velocity and of the term K of stars of type B with distance.

Dikran G. Dervichian and Maurice Joly: Homogeneous transformation points in monomolecular layers.

Constantin Salceanu and Corneliu Istraty: The determination of the positions of resonance in tubes by means of a galvanometric deviation. An application of the resonance method of Bungetzianu, in which the telephone method of defining the resonance positions is replaced by a galvanometer method. Results obtained with water, alcohol, acetone and carbon tetrachloride are given graphically.

Raymond Zouckermann: The variations of the explosive potential of a discharge tube without internal electrodes, under the influence of ultraviolet or visible light. The curve showing the relation between the explosive potential in hydrogen, in a tube with external electrodes, and the pressure of the gas, is changed when the gas is exposed to light, the explosive potentials being always lower in the latter case. The cause of this phenomenon is obscure.

Amédée Guillet : Vagueness in the working of systems formed, like the microphone and the coherer, of a large number of associated elementary contacts.

Mlle. Milka Radoïtchitch : The influence of the solvent on the infra-red absorption spectra of various solutions of neodymium and samarium acetylacetonates. The infra-red absorption bands of salts of the rare earths in solutions of organic solvents undergo displacements and variations of intensity depending on the solvent, a result analogous with that already found in the visible spectrum.

Maurice Parodi : Study of the transmission of some benzene derivatives in the extreme infra-red.

Pierre Grivet : The modulation of light at high frequency. Its application to the measurement of very short periods of time.

Jacques Rabinovitch : The magnetic double refraction of benzene solutions of the pinenes.

Mlle. Yvette Cauchois and Mlle. Marie Louise Allais : The L spectra of emission and absorption of thorium and its characteristic levels.

Pierre Auger : The new heavy particles of cosmic radiation.

Marc Foëx : The solubility of oxides in fused boric anhydride at 1200° C. Experimental data for the solubility of various metallic oxides in fused boric oxide at 1200° C. are given. From the figures it is concluded that the solubility of the oxides varies regularly with the molecular weight. Several oxides, hitherto considered as insoluble in fused boric oxide, have in reality an appreciable solubility.

Guy Gire and François Fouasson : Basic selenates and tellurates.

François Olmer : The reduction of the oxides of iron by carbon monoxide in the presence of some natural impurities. The catalytic action of iron on the decomposition of carbon monoxide is impeded, or even entirely stopped, by the presence of phosphoric anhydride or of alumina.

Jacques Parrod : A reaction of ethyl dihydroxymalonate. Application to the detection of mesoxalic acid. The reaction between ethyl dihydroxymalonate, zinc sulphate and ammonia produces an intense green fluorescence.

Gaston Gibault : The magnetic disturbance of January 25, 1938.

Charles Maurain : Remarks on the preceding communication.

Roger Faillettaz : An anemometer with photoelectric cells for the study of atmospheric turbulence.

Robert Bureau : Ionospherical disturbances starting suddenly and their effects on the long waves.

Marius Chadefaud : The plasts and amylogenesis in the Dasycladaceæ.

Georges Mangenot : The oospheres, the pollen tubes and fertilization in the maritime pine.

Antonin Tronchet : The optical properties of the papillous cells of the tendrils of *Eccremocarpus scaber*.

M. and Mme. Fernand Moreau : The hormonal formation of the perithecium in the Neurospora.

André Hollande : The parabasal apparatus of the Cryptomonadines.

Maurice Fontaine and René Guy Busnel : The localization of the role of flavine or of a body similar to flavine in the skin of fish.

Antoine Magnan, Charles Perrilliat-Botonet and Henry Girerd : Simultaneous cinematographs in three perpendicular directions, two by two, of a bird in flight.

Serge Tchakhotine : Experimental parthenogenesis of the egg of the *Pholas* by ultra-violet micropuncture, terminating with a living larva.

Marcel Mazille : A dry and irreversible dialysis of blood serum.

Alexandre Besredka : The disappearance of the vaccinating power of diphtheric anatoxin in the presence of antidiphtheric serum. Whilst the anatoxin, injected alone, exerts an immunizing power, it ceases to have this influence in the presence of antidiphtheric serum. The animal behaves as if the anatoxin were annihilated by the serum.

Henri Violle : Contribution to the study of endemic exanthematic typhus.

P. G. Charpentier, Maurice Doladilhe, Charles Morel and Louis Placidi : The anaphylactizing properties of the blood serum are localized in the viscous protein of this serum.

Prague

Czech Academy of Sciences and Arts

January 15, 1937.

J. Milbauer and J. Vodrážka : Simultaneous estimation of SeO_3'', SeO_4'', AsO_3''', AsO_4'''. Arsenates are precipitated by magnesium solution, arsenites are oxidized to arsenates by ammoniacal H_2O_2 ; selenates are estimated as $BaSeO_4$ by using $Ba(ClO_4)_2$ instead of $BaCl_2$.

Fr. Kostečka : Transplantation of tooth germs.

R. Brdička : The application of the polarographic protein reaction for cancer diagnosis. The polarographic estimation of proteins in blood serum shows that the results in cases of cancer are distinctly lower than in normal cases, provided that time is allowed for the denaturation of the proteins.

J. Goll : Metallography of nickel ores from Dobšina.

K. Žebera : The Cretaceous formation at Kladno.

Fr. Fučíková : An anthropometric contribution to rib morphology.

March 12, 1937.

Fr. Němejc : The cone called Discinites Feistmanteli.

J. Wolf : The surface relief of resorption cells.

E. Votoček : The carbohydrates of papyrus pith (*Cyperus papyrus*).

E. Votoček and R. Muller : New reagents for the identification of ketoses.

E. Votoček and O. Wichterle : Additive products of hydrocyanic acid, glycosylarylamines, and glycosylpiperidines.

B. Němec, J. Babička and I. Smoler : Spectroscopic and chemical estimation of gold in plants. The amount of gold in the ashes of various plants was determined, and found to be surprisingly high in some specimens.

Z. Kocher : The influence of higher sulphonated alcohols on the resorption through the epithelium of the gastro-intestinal tract.

J. Korous : Development of the functions of one real variable into a series of certain orthogonal polynoms.

V. Rypáček and T. Martinec : Dependence of the titration acidity of soil suspension and soil filtrate on the size of the soil particles.

R. Kettner : Geological structure of the northern slope of Kralova Hole near Liptovská Teplička (Low Tatras).

Forthcoming Events

Thursday, April 7

BRITISH MEDICAL ASSOCIATION, at 8.—Dr. H. Crichton-Miller: "Mental Health as a National Problem" (Sir Charles Hastings lecture).

INSTITUTION OF NAVAL ARCHITECTS, April 6–8.—Annual meeting to be held at the Royal Society of Arts, John Street, Adelphi, W.C.2.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

PROFESSOR OF EDUCATION in the University of Cambridge—The Vice-Chancellor (April 18).

LECTURER IN HYGIENE AND BIOLOGY in the Avery Hill Training College, London, S E.9—The Education Officer (H.2/1), County Hall, London, S E.1 (April 30).

UNIVERSITY LECTURER IN GEOGRAPHY in the University of Cambridge—Dr. F. C. Phillips, Department of Mineralogy and Petrology, Cambridge (April 30).

UNIVERSITY READER IN MATHEMATICS in the Imperial College, Royal College of Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 2).

DEMONSTRATOR AND ASSISTANT LECTURER IN CHEMISTRY in the Royal Holloway College, Englefield Green, Surrey—The Principal (May 7).

JUNIOR LECTURER IN METALLURGY in the University of the Witwatersrand—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (May 31)

Blood and Soil

THE history of mankind is largely a story of the conflict of man's ideals, or, as the cynic would say, of his illusions. Of these the most potent, and in the long run the most enduring, are those affording the herd instinct fullest opportunity for play. This instinct, binding individuals by a bond of brotherhood in communities armed at all points for attack and defence, is at once self-regarding and altruistic. Appealing to both sides of human nature, in the struggle for existence it is the most effective of all the means of survival.

Among manifestations of the herd instinct the concept of 'race' has played a greater part in the development of modern civilization than any other factor, except perhaps religion. It is capable of wide extension ; and on occasion it over-rides the closest and most intimate ties, even, paradoxically enough, those of the family, from which it takes its origin. For the apotheosis of 'race', which is the very heart of the aggressive nationalism of modern Europe, derives the strength of its appeal, not so much from tribal origins, as from the blood-call which goes back to the intimate association of the primitive individual family and its blood-relationship. It is this tie which by a process of enlargement provides the binding force and the emotional colour in the progression of social organization from family to kin, tribe, people and nation ; and when transferred from the group to the territory it occupies, is capable of inspiring the noblest self-sacrifice and deeds of the loftiest patriotism. Cultural association and religious tradition undoubtedly play their part ; but the ever-recurrent theme is the blood-tie.

Recent events in Central Europe have demonstrated how the racial idea could add dynamic force to a political movement for which neither historic tradition nor economic advantage had inspired adequate enthusiasm. In his speech before the Reichstag on March 18, Herr Hitler, reviewing the course of events of the preceding week, described the incorporation of Austria in the German Reich as "a racial triumph", and the culmination of a movement of "national-thinking people—to set up in place of a lying democratic violation of a people, the more holy rights of the eternal racial life". The sanctity of the racial life is to be further impressed on the population by the extension forthwith of German racial legislation to Austria.

To those who hold to the ideal of individual liberty and freedom of thought as the fundamental principle in intellectual and social progress, though they may admit the dynamic force inspired by a thoroughgoing acceptance of the racial idea, the intolerance, arrogance and injustice apparently inseparable from the discriminations of racial doctrine, when harnessed to political action, are wholly repugnant. What could be more significant as an example of the repression of individual judgment and the arrogant assumption of a right to eliminate the free expression of opinion, than Dr. Goebbels' own words, commenting on the statement that criticism was not allowed in Germany. They had no objection to criticism, he said, but it must be criticism from the superior to the inferior (*The Times*, March 23).

Germany does not stand alone. Wherever in social contacts discrimination has been imposed on the basis of racial groupings or the colour line—purely physical distinctions, be it said—these distinctions are made, unjustifiably, an imputation of innate inferiority, both intellectual and moral, in the excluded race or group. So it is said by a member of a people so highly race conscious as the Japanese, "From the fact of the divine descent of the Japanese people proceeds their immeasurable superiority to the natives of other countries"; thus the scholar Hirata, while the learned publicist, Dr. Uesugi Shinkichi, holds "it is now most clear that the salvation of the entire human race is the mission of our Empire".

Aryan doctrine perhaps has not yet gone so far as this except by implication, though its upholders maintain that all progress in civilization has been the work of the Aryans, of whom the German people as Nordics are the characteristic modern representatives. No student of European prehistory and ethnology, outside Germany, could endorse this claim. It is not known either that the Aryan-speaking peoples were racially homogeneous, all conforming to the Nordic type, nor would it be accepted as probable that a nomad pastoral people, such as the Nordics on their first appearance on the scene, were pioneers of a higher culture, when they impinged, for example, on the Minoan civilization of the Mediterranean, or the 'Dravidians' of India.

The discussion of innate racial superiority and inferiority in mental character is bootless. Too little is as yet known of racial psychology to justify a correlation of mental and physical characters, which would warrant the imputation of mental and moral superiority or inferiority in certain types of physical make-up. Even difference in cultural level—the state of backwardness—has yet to be shown to be a sign of inferiority in innate intellectual calibre. Investigation, so far as it has gone, affords no sufficient ground for the conclusion that 'primitive' peoples are intellectually stunted, even though their mental processes are environmentally conditioned; and it would be difficult to accept any assumption of inferiority where the members of the two racially contrasted groups have grown up and lived in an identical cultural environment, as have most of the Jews who have been expelled or excommunicated of late years in Central Europe. Even if, however, it were possible to correlate certain types of mental character with racial characters, the doctrine, if carried to its logical conclusion, demands purity of racial type, which, indeed, German policy would now seem to regard it as its aim to make coterminous with 'nation'. But most anthropologists hold the 'pure' race a fiction, while 'the racial type' in this context can only be regarded as an ideal, towards which peoples are continually evolving. This is apparently the view of Sir Arthur Keith, when he maintains that a race is a nation in the making. Even in Germany, however, though the extent of the broad-headed element has been consistently minimized, the existence of mixed types has always been admitted; while even recently it has been advanced that a blonde pigmentation is not an essential criterion of Aryan descent. In fact, in the theory of a pure Aryan race, of which the Germans are the descendants, Nazi doctrine appears to have slipped into the familiar fallacy of translating the ideal at which it aims into a pseudo-historical fact of the past.

To be of any scientific value, 'race' as an entity must be susceptible of exact definition; but anthropologists are by no means agreed as to the criteria and precise value of the term. That there are such differences in physical character and appearance between individuals as to afford a strong presumption of ancestry and origin, and, therefore, in that partial sense racial, is a matter which, as Sir Arthur Keith is fond of pointing out, can be verified by anyone who walks down the street. If, however, an attempt is made to analyse the basis of this judgment, more often than not it will be found to depend to a large extent upon colour, primarily of the skin, then of hair, and then eyes. An entertaining and instructive exercise is to imagine a white skin on some of our darker fellow-subjects encountered in street and train. It is surprising to find how often even an African might in feature pass for European, if the lips are not too thick. Yet there may be nothing to suggest European admixture. At the same time the Mongolian fold over the eye usually betrays the eastern Asiatic; yet occasionally it is found with other Mongolian facial characters in Europeans, both normal and abnormal.

On one fact anthropologists are agreed. Modern man belongs to one species, *Homo sapiens*, and that in this species are many varieties, or races, but that none of these can now be regarded as 'pure'. For purposes of classification and analysis, these varieties are grouped in terms of type, according to physical characters recorded by measurement and descriptive observation; but these racial types are abstractions for methodological convenience. When this type classification is applied to observation in the field, it is found that any given group no more than tends to conform to type within a certain range of variation. In effect, man is the most variable of all animals. The most that can be said of the races of man is that within the range of his variation at certain points certain physical characters show a tendency to become dominant, forming a nucleus, which for purposes of convenience is regarded as a racial type.

It by no means follows that this type is either universal within its area, or confined to it. In Europe, for example, Nordic, Alpine, Mediterranean may be the dominant types within the regions from which they take their respective names, but they are inextricably intermingled in varying proportions throughout the whole continent. Nordics and Alpines appear in Mediterranean lands, dark and broad-headed among the long-headed, blonde Scandinavians. For from the dawn of civilization, Europe has been swept from end to end by racial migrations and invasions, which have left their legacy in an inheritance of fused racial characters, while in modern times facilities of transport and a freedom of intercourse in international relations have further tended to confuse the geographical distribution of physical type and racial distinction. In these conditions the racial type becomes a theoretical postulate and purity of race a claim without counterpart in fact. Nor do these conditions prevail in Europe alone. Ever since time began, man's wanderings and his conquests have tended to obliterate distinctions which isolation, inbreeding and tribal prejudice promoted and preserved, until only broad distinctions remain valid.

Acceptance of the strict biological view of race and the inheritance of physical characters in man does not preclude recognition of the patent fact that there are differences, some of them considerable, between the national and other local groupings of man which afford ostensible support for nationalist doctrine ; but they are due to environmental conditions rather than a physical inheritance. If, moreover, in physical character modern man is specifically one, it is no unfair assumption, unless due cause is shown to think otherwise, that in mental character man is also one, and that underlying cultural differences, which can be shown to be due to environmental and historical causes, there is a psychic unity, which can at need transcend nationalist and other separatist influences. In science, for example, man speaks a universal language and joins in a world-wide activity.

It is evident that in the development of the social organism from the primitive horde or individual family to the nation, the differences between local and other groupings have been subordinated to such elements as they have in common, in order that other groups, ever increasing in size and complexity, may be formed, in which, when once internal harmony has been established, the good of the whole may be pursued. Out of such groupings for a common end the modern civilized nations have arisen ; and there is no inherent reason, so far as scientific studies of the growth of societies would go to show, why development should come to an end at the point which it has now reached. There have been, in fact, in recent years two experiments in carrying development further. Of these one is the British Commonwealth of Nations, which has still to be submitted to a crucial test, the other the League of Nations, which, apart from its more widely advertised political action, has done a great work in science, economics and social reform for the advancement of the interests of mankind at large. In these fields of its activity, racial and national differences have proved no bar to co-operation, even though the time is not yet ripe for the joint political action which it was hoped that the League would promote. It is to some such larger unity that the scientific analysis of the history of human associations would appear to point as the goal of the future, rather than to an antagonism of rival national or racial entities, engaged in a struggle which belongs more properly to a pre-social stage of development.

In its origins science is one form of the response to man's eternal quest for law and order in the universe ; but from the earliest times it has also served his material needs. When primitive man first observed the ordered movement of the stars, it was not so much in satisfaction of a divine curiosity, as from the desire to arrive at some such law of seasonal progression as would enable him so to order his life as to ensure the proper care of flocks and herds and the sowing and harvesting of his crops ; and so in the world of modern civilization. Knowledge may be pursued for its own sake, but it is no less the function of science to share in that planning for the future, which the development of social and economic organization makes more and more imperative every day. If, however, the study of man, his kinds and varied modes of life is to contribute to the solution of our problems, as it is only reasonable to anticipate, it must be as a study based on impartial and objective observation of fact, and not the forcing of fact to fit a biased and distorted political dogma born of fear and hatred—a science travestied in masquerade.

Health Services of Great Britain

Report on the British Health Services:
a Survey of the Existing Health Services in Great Britain with Proposals for Future Development. (P E P (Political and Economic Planning).) Pp. iv + 430. (London: Political and Economic Planning, 1937.) 7*s.* 6*d.* net; cloth, 10*s.* 6*d.* net.

THIS large and heavy book of 430 quarto pages, said to contain 200,000 words, is described by its anonymous authors as a survey of the existing health services in Great Britain, with proposals for future development. The writers constitute an independent, non-party group of industrialists, distributors, local government officials, medical men, university teachers, and so forth, "who give part of their spare time" to social and economic studies, and issue fortnightly 'broad-sheet' plannings.

Early in the nineteenth century, the sanitary services of Great Britain were strengthened and invigorated by the introduction, and ultimately the Parliamentary imposition, of what have come to be known as 'special medical services'. It was a new factor or method of dealing with the national ill-health. Speaking generally, it began with the Poor Law medical service, originating in the Elizabethan period, and that deeply instructive movement led on to factory and workshop reform dating from 1802, to the registration of births and deaths, vaccination, and official inquiries into the causes of epidemic disease. It found legislative expression in a long series of Public Health Acts, the development of 'the sanitary idea' and the beginnings of a 'sanitary conscience'. It was Disraeli who coined his party's watchword, *sanitas sanitatum et omnia sanitas*; and it was Sir John Simon who gave us the classic record of the administrative rise of "English Sanitary Institutions" in 1890.

The foundations of all the British health services were laid before the present century opened, yet it was not until after the great Education Act of 1902 that they took their present form, the form which is discussed in this volume. But there can be no wise or mature consideration of their existing basis or purpose without a historical understanding of their origin. In our own day, and particularly since the Liberal Government of 1906, there has been wide and rapid growth of these services. The feeding and medical supervision of school children, maternity and child welfare, old age pensions, health insurance—with 19,000 panel doctors and nineteen million insured persons —a vastly enlarged hospital service (voluntary and municipal), industrial health, a reorganized medical profession, medical education, dentists, official midwives, nurses, sanitary inspectors, physical education, organized research—all this is novel and in the early process of initiation and administration.

No responsible body has previously attempted the very formidable task of showing how these services work, are co-ordinated, and can be conjunctly developed. This compilation furnishes a mine of important and interesting information, derived in the main from official reports, local and central. It is an encyclopædic summary, made lively by numerous criticisms, not all equally valid or well conceived. Indeed, occasionally it would appear that the writers would greatly enjoy the task of re-creating *ad hoc* the growth of two centuries, not only of Parliamentary legislation but also of the will and education of the English people. In which case it may be added that they are not alone, in Great Britain or in Russia.

More than fifty years ago, one of our foremost statesmen, trained in a long experience of the diplomatic service, reminded us that the basis of all government and the object of all statesmanship must always be *expediency*—that which is, on the whole, best for the entire community. He urged that the test of statecraft is not truth or falsehood, but good or evil. All political action, in his view, was good or bad, right or wrong, according to its consistency not with theory but with *circumstance*, and such circumstance is not simple, uniform, general or consistent, but infinitely varied, fluctuating and divergent. We cannot, he said, apply to courses of political action or administration the methods which are properly applicable to trains of reasoning, for the object of the latter is to arrive at abstract truth, of the former to bring about concrete good of a particular kind for a particular multitude of human beings, whose condition is extremely composite and whose interests are rarely identical. "Government", he believed, "is neither more nor less than the trustee or guardian of the collective interests of a State. Institutions are not made, they grow, not logical, simple or symmetrical, but various, intricate and full of salutary anomalies". Hence in a general review of statecraft it is prudent to proceed with caution, and have regard to history, experience, circumstance and expediency; and, especially when dealing with the administration of science and the scientific method, to keep in mind the existing state of science itself.

This summary of the existing health services of Great Britain, official and voluntary, is the best we have seen, and its compilation ought to serve and assist all who are actively concerned in actual administration. It is unfortunate, perhaps, that it is inadequately documented and lacks a bibliography. The reader is left with a large volume by an anonymous, and apparently self-appointed, group of zealous students, and without reference to the sources of information. The book itself is clear evidence of the competence of its writers and the reader is assured of the authenticity of their resources. We rather agree, however, that such a survey should have been undertaken by an officially appointed or approved body, and not anonymously. Its appeal is mainly to the local authorities and their officers, who are accustomed to the English practice of signed reports by responsible persons. But in any event, here is a book which provides the reader and student with a most valuable, instructive and comprehensive presentation of the facts.

For the reason just mentioned, and for other obvious reasons, including finance, we fear the numerous recommendations and proposals made throughout the report, many of them acutely controversial, are less likely of acceptance. The public will naturally consider the suggestions regarding the medical profession as a matter primarily for its members, through the General Medical Council and the British Medical Association; midwives, nurses and dentists have also quite recently received much Parliamentary attention; nutrition and physical education are, it is to be hoped, fairly on the way to reform; the various suggestions for the improvement of health insurance have already been before a Royal Commission; and some of the more abstruse medical problems await further knowledge and experience.

We welcome the interest of the writers in the importance of medical research. Certainly, there is always need of more knowledge. Yet in a single generation we have witnessed, at any rate since 1911, a great awakening and an ever-extending appreciation of that need. The fundamental difficulty is lack of researchers, for true research can only be done by those who have the talents and experience which especially fits them for it. Often, the indirect approach is the more effective; the human body is immeasurably complex and all sciences affect the issue, which is rarely medical only. Physics, statistics, biology, geology, may be as material as physiology or pathology, and the relation of the sciences to each other and to the whole is highly relevant to the acquisition of more knowledge. Facility and opportunity—ways and means and money—are rapidly becoming more available. New and further knowledge cannot be gained by pressure or administrative organization. Even now much scientific knowledge awaits application rather than elucidation. Nor is there any doubt that it is common knowledge among responsible officers in the health services that health and ill-health bear intimate relation to social condition, economics and psychology, and this is now more appreciated than formerly.

Organo-metallic Compounds

Die Chemie der metall-organischen Verbindungen

Von Prof. Dr. Erich Krause und Prof. Dr. Aristid von Grosse. Pp. xvi + 926. (Berlin: Gebrüder Borntraeger, 1937.) 55.20 gold marks.

FROM the time of their discovery, the organo-metallic compounds have aroused particular chemical interest. The manner in which they were first encountered was dramatic. Edward Frankland, working in Bunsen's laboratory in 1849, was attempting to isolate the radical methyl by heating methyl iodide with zinc in a sealed tube. "After discharging the gases" he says ("Sketches from the Life of Sir Edward Frankland", p. 186), "I cut off the upper part of the tube in order to try the action of water upon the solid residue. Upon pouring a few drops of water upon this residue, a greenish-blue flame, several feet long, shot out of the tube, causing great excitement in the laboratory. Bunsen, who had suffered from arsenical poisoning during his researches on cacodyl, suggested that the spontaneously inflammable body might be that terrible compound formed by arsenic present in the zinc as an impurity, and that I might be already irrecoverably poisoned."

Fortunately Bunsen was wrong. The inflammable compound was not cacodyl but zinc methyl, and Frankland survived the incident by more than fifty years. The discovery of the alkyl compounds of zinc was quickly followed by that of similar derivatives of mercury, tin and antimony, and consideration of these substances led Frankland to make his great contribution to chemical theory—the law of valency.

At the beginning of the present century, two events gave a powerful stimulus to the investigation of organo-metallic compounds. These were

Grignard's discovery in 1900 of the organo-magnesium halides, and that of Ehrlich in 1907 of salvarsan. The extraordinary value of the Grignard compounds as synthetical reagents led to their exploitation in all possible directions and brought notable advances in many fields of organic chemistry, whilst Ehrlich's discovery laid the foundation of the new science of chemotherapy, and by inspiring the search for new therapeutic agents led to an active investigation of the organic derivatives not only of arsenic but also of mercury and antimony. Of some 12,000 known organo-metallic compounds, about 8,000 are derivatives of arsenic.

The most abundantly utilized organo-metallic compound is lead tetraethyl ('Ethyl'), on account of its 'antiknock' properties discovered by Midgeley in 1922. More than 70 per cent of the petrol consumed in the United States for automobile propulsion in 1936 had received an addition of lead tetraethyl, and the annual consumption of this compound in the U.S.A. alone amounted to some 20,000 tons. In Germany, however, iron pentacarbonyl ('Motalin') is chiefly employed as an antiknock.

Of the purely scientific applications of organo-metallic compounds probably the most striking is that made in Paneth's work on the thermal decomposition of the alkyl compounds of lead and bismuth, by which it was shown that the radicals methyl and ethyl are capable of independent though brief existence.

The book under review is a treatise of more than 900 pages. Organo-metallic compounds are defined as containing a metal linked by a principal valency to the carbon of a hydrocarbon radical. Co-ordination compounds are thus excluded, but arsenic and tellurium are counted as metals and the alkyl compounds of oxygen, sulphur and selenium, and of the halogens, nitrogen and phosphorus are shortly described for comparison.

The derivatives of the four elements the organic compounds of which have been most extensively investigated—magnesium, mercury, arsenic and antimony—are treated in considerable detail (for example 143 pages are devoted to arsenic compounds) but are not dealt with exhaustively, since this is naturally impracticable within the limits of a single volume (and the authors suggest that it is the less necessary since excellent monographs dealing with these elements are already available.) They claim, however, that of the remaining metals, all known compounds are included so far as they appear in the literature abstracted in the *Chemisches Centralblatt* down to January 1, 1936.

Physical data are fully recorded, but the authors deplore that the only properties which have been hitherto at all extensively determined are boiling points, melting points and densities. They point out that the alkyl compounds of the elements, providing a series of mostly normal liquids, free from disturbing effects of association and co-ordination, form material of exceptional value for the study of the variation of the combining properties of the elements over wide regions of the periodic table, and they stress the desirability of obtaining more complete data derived from the newer methods of investigation (for example, Raman spectra, at present available only for limited groups) in order to enable a general comparison of the more fundamental properties of the links which the elements form with alkyl groups.

A chapter is devoted to theoretical considerations on the organo-metallic compounds. Of the ninety known elements, only about forty form alkyl derivatives. The transition elements lack the power of combining with hydrocarbon radicals, for of the forty-two elements of this category only two—platinum and chromium—have been definitely found to yield alkyl or aryl derivatives. The authors correlate this with the fact that the transition elements, unlike other elements, have their valency electrons distributed between two principal quantum groups. In titanium, for example, which forms no organo-metallic derivatives, two of the four valency electrons are in the M- and two in the N-shell. To explain the incapacity of such elements to combine with hydrocarbon radicals, the authors suggest that when the valency electrons are in two principal quantum groups, those with the lower principal quantum number yield antibonding molecular orbitals. This explanation is conceivable, but scarcely probable. The transition elements differ from other elements in having d-electrons among their valency electrons, and it may be that the character of the d-wave functions is such that they do not combine with s-wave functions to give bonding orbitals of the necessary strength. In any event the explanation is likely to be more subtle than that suggested.

The descriptive parts of the book are well and clearly arranged, and the experimental aspects of the subject receive special attention. Detailed directions are given for the preparation of representatives of the chief types of organo-metallic compounds, and a number of devices are described that have been found useful in the manipulation of substances which, like so many members of this class, are specially sensitive to atmospheric oxidation.

This treatise is to be commended as a book of reference which should prove most valuable to all workers in the field with which it is concerned.

W. H. M.

Descriptive Zoology

Handbuch der Zoologie:
eine Naturgeschichte der Stamme des Tierreiches. Gegründet von Prof. Dr. Willy Kukenthal. Herausgebenen von Dr. Thilo Krumbach. (Berlin und Leipzig: Walter de Gruyter und Co., 1937.)

(1) Band 3, Hälfte 2: Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 10, Teil 5. Pp. 7–134. 18 gold marks.

(2) Band 3, Hälfte 2: Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 9, Teil 2. Pp. 289–384. 12 gold marks. Band 3, Hälfte 2: Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 11. Pp. 385–496. 16 gold marks.

(3) Band 5, Hälfte 2: Tunicata. Lief. 6. Pp. 545–672. 18 gold marks.

(4) Band 6, Hälfte 1: Acrania (Cephalochorda) = Cyclostoma, Ichthya. Bearbeitet von Dr. Victor Pietschmann. Lief. 5. Pp. 449–560. 14 gold marks.

(5) Band 7, Hälfte 1: Sauropside, Allgemeines; Reptilia; Aves. Lief. 3. Pp. 225–320. 14 gold marks.

(1) THIS well-known general "Handbuch der Zoologie" revives the term Vermes, which has practically ceased to be used in English texts. The Vermes are divided into three groups, the Amera, Polymera and Oligomera. The present part is the first of the section of the book to treat of the Oligomera. This group includes three classes: (1) Tentaculata, that is, the Phoronidea, Bryozoa and Brachiopoda; (2) Sagittoidea (Chaetognatha); and (3) Brachiotremata, that is, the Pterobranchia and Enteropneusta. The first sixty pages contain an introduction to the Oligomera, including a bibliography of general works. The next four pages are an introduction to the Tentaculata in particular, and the last sixty-four pages furnish a complete and most useful account of the Phoronidea up to the first few items of the special bibliography of that group. The whole part contains 150 well-produced figures, a good number of which are original. A curious error has crept in on p. 123. No. 24, *Phoronis pacifica* is correctly stated to be Puget Sound and Humbolt Bay, but on the map point 24 is depicted on the east coast a little south of New York.

(2) Part 9 of this half of the second volume contains 116 illustrations. The first eleven pages conclude the account of the Solifugidæ by A. Kästner and are mainly concerned with the distribution, classification and literature of the group. Ten families in all are recognized and defined, and a useful key for separating them is provided. The bulk of the part is concerned with A. Kästner's account of the Opiliones, up to their geographical distribution.

The first nine pages of Part 11 carry on from Part 9 and conclude the Opiliones. It contains little more than a review of the families and subfamilies, among which the more than 1,400 species of the order are divided, and the list of the relevant literature. The remaining hundred and three pages commence the account of the Araneæ, or true spiders, by U. Gerhart and A. Kästner. It deals in detail with the general morphology, anatomy and histology of the group up to the beginning of the female reproductive organs—the reproductive system being the last to be considered. The part is illustrated with 133 figures, a number of which are original.

(3) In Part 6 of the second half of the fifth volume Dr. Johan Huus deals with the Ascidiaceæ or simple Ascidians. It contains 123 figures, mostly, with the exception of the distributional maps which are original, chosen from the works of previous writers. It completes the account of the structure, physiology and ecology of the sub-class and also a large part of the systematic review of the genera, but does not include the bibliography.

(4) The first hundred and two pages of the first part of volume 6 complete the account of the Cyclostoma by Dr. V. Pietschman. It has thus taken five hundred and fifty pages and 531 figures altogether to deal with this group. Without in any way suggesting that it is an uninteresting or unimportant group, it would seem that such treatment exceeds in length and detail what is usually expected of a "Handbuch". In itself it forms quite a substantial volume, and the various parts together cost 68 gold marks. It is obviously impossible to treat all the groups of the animal kingdom at this length. As it stands, it forms a veritable mine of information and has a most useful bibliography. The last ten pages commence the general account of the Ichthya or true fishes.

(5) The first eleven pages of this part conclude Proj. O. von Wettstein's account of the order Rhynchocephalia. It is naturally based on the genus *Sphenodon*, of which only one living species, *punctatus*, is recognized, although several varieties are described. Brief reference is made, however, to the allied fossil orders, Choristodera and Rhynchosauroidea. The whole account of the order occupies two hundred and thirty-five pages, is illustrated by 174 figures, and terminates with a most useful and full bibliography. The remainder of the part deals with the Crocodilia.

Economic Botany:

a Textbook of Useful Plants and Plant Products. By Albert F. Hill. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Pp. x+592. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 24*s*.

IN this work, the author, who is research assistant in economic botany at Harvard University, deals in an interesting manner with the more important useful plants and plant products of the world from the point of view of their history, cultivation, preparation and utilization. He shows how the three great necessities of life—food, clothing and shelter—as well as a large number of other useful products, are supplied in great measure by plants. Economic plants have been intimately bound up with human existence and have not only played an important part in the everyday life of mankind but have also had a profound influence on the course of history and civilization. Spice plants and the early spice trade afford evidence of this.

The volume consists essentially of four main sections: industrial plants and plant products; drug plants and drugs; food plants; and food adjuncts. Under the first of these are fibres, forest products and resources, tans and dyes, rubbers, gums and resins, essential oils, fatty oils and waxes, sugars, starches and cellulose products. Food plants include cereals, legumes, nuts, vegetables, fruits, spices and beverage plants. Insecticides such as pyrethrum, derris and cube (*Lonchocarpus*), which have assumed increasing importance in recent years, are also dealt with. In all, about eight hundred species are referred to, greater stress being laid on those plants that are of particular importance in the United States. There are numerous photographs in the text, and a full index and bibliography of more important works are given.

Introduction to Theoretical Seismology

By J. B. Macelwane and F. W. Sohon. Part 1: Geodynamics. By J. B. Macelwane. Pp. x+366. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 30*s*. net.

AS the author remarks, "the forces producing earthquakes, the character and structure of the rocks affected, and the permanent displacements occurring in them are geological phenomena". They form the subject of seismology proper, and have been well described in Heck's recent work on "Earthquakes" (see NATURE, March 27, 1937, p. 529). The subsequent course of the waves so produced and the physical properties of the media through which they pass form a distinct branch of science to which the present volume is devoted. Depending to some extent on older works, such as Galitzin's "Vorlesungen über Seismometrie", this book is a summary of lectures delivered by the author. With its companion volume on "Seismometry", by F. W. Sohon, it forms a text-book that will be of great value to students of geophysics.

In the first seven chapters, dealing with stresses and strains in elastic solids and the course of seismic waves through the earth, the treatment is almost entirely mathematical. The last four chapters are, however, of interest to the general reader. They describe the paths of seismic rays, the interpretation of seismograms, and, especially, the methods by which the positions of epicentres and the depths of foci are determined. Many useful tables are given, such as those of the velocities of waves in the different layers of the crust, the positions of important seismological stations, and the notation used in denoting the various phases that appear on a seismogram.

C. D.

Tables Annuelles Internationales de Constantes et Données Numériques:

International Annual Tables of Constants and Numerical Data. 14: Combustion and Detonation of Gases. By Prof. P. Lafitte. Vols. 11–12 (Years 1931–1936), Section 70. Pp. iii+28. (Paris: Hermann et Cie.; New York: McGraw-Hill Book Co., Inc., 1937.) 16 francs.

THE summary of constants and data relating to the combustion and detonation of gases contained in vols. 7, 8 and 10 of the "Tables Annuelles Internationales de Constantes et Données Numériques" has been brought up to date by Prof. Lafitte in vol. 14, which covers the years 1931–36. This period is noteworthy for many important advances in the subject, inspired to a large extent by Semenoff's development of the chain-reaction theory. Chain mechanisms of hydrocarbon combustion have been suggested by Egerton, Norrish and Lewis, and new phenomena indicative of chain processes have been discovered in relation to ignition, the limits of inflammability and detonation; in addition, there has been a general revision and extension of existing data.

Prof. Lafitte has used excellent judgment in assembling and summarizing the results of this large body of new information. The numerical data are tabulated or are given in the form of curves reproduced on a legible scale, and each of the ten sections into which the volume is divided is accompanied by a comprehensive bibliography. D. M. N.

Contes Lazes

Par Georges Dumézil. (Université de Paris: Travaux et mémoires de l'Institut d'Ethnologie, Tome 27.) Pp. xii+134. (Paris: Institut d'Ethnologie, 1937.) 56.25 francs.

THIS collection of folk-tales from the Caucasus has a double interest. To that of the folk-lore content is added that of the linguistic material. The volume contains a collection of tales related to the author in Constantinople by a young Georgian, a native of Lazistan, in his own language. The themes, for the most part, are familiar, but the tales are told with a delightful naiveté. Some, as the author points out, probably have a literary origin. From the scientific point of view the chief value of the collection lies in the linguistic analysis of the little-known language of Lazistan. The author provides an interline, as well as a running, translation and a grammatical commentary.

Scientific Work of the Drifting North Polar Station*

By P. Shirshov and E. Fedorov

EXACTLY a year ago we were preparing for the press an article on the plans we had made for our scientific work on the drifting icefloe. This article was published after the aeroplanes had landed us at the North Pole. It is pleasant to note that everything we had planned to do before we set out on our expedition has been done. Reality brought us much of the unexpected. In particular, the drift turned out to be more rapid than we had anticipated. In consequence, we were able to carry out observations at a considerably greater number of points than was originally planned. Over a distance of 15°—from the Pole to the 75th parallel—we carried out all the work we had set out to do. From February 1, after our icefloe had split, we were compelled to cease hydrological work, because the winch, which was kept about a kilometre from our tent, was carried away.

Owing to the rapidity of the drift, we were compelled to make more frequent observations than had been planned. To cope with the work was only possible because our colleagues—Papanin and Krenkel—relieved us of all domestic duties, which they took entirely upon themselves. Naturally, work like the measurement of the depths, rotatory and other observations, was carried out by the joint efforts of the four of us. Meteorological observations were carried out by Fedorov and Krenkel.

Every observation we made during the drift had to have an exact position. Therefore we endeavoured to determine our longitude and latitude as often and as carefully as possible. For these determinations we had to measure the height of the luminaries above the horizon. During the 274 days of the drift we took 534 series of measurements, from which we calculated our positions at 143 points. These points served as the basis for the entry of our course on the map. Up to the end of September, for astronomical determinations we made observations of the sun and sometimes of the moon. Later, when the oncoming darkness permitted us to see the stars, we always used the latter for our observations. Cloudy weather sometimes left us without a position for six or seven days at a stretch, but happily this did not often occur.

The study of the movement of the ice covering the surface of the Arctic Ocean was one of the most interesting subjects of our work. During the 274 days, we went from lat. 89° 26′ N. and long. 78° W. to lat. 70° 48′ N. and long. 19° 48′ W., covering 1,134 miles (1,800 kilometres) to the south-south-west (more precisely, a course of 197°) reckoning by the shortest line. The numerous zig-zags and loops, especially in the early days, actually lengthened our course, bringing it up to approximately 2,500 kilometres. Consequently, the average speed of drift of the icefloe was 9·1 kilometres or 5·6 miles a day. Though this was the average speed of our movement, actually the movement varied greatly. There were periods when for two or three days we remained on the same spot, and others when we drifted 23 miles (37 kilometres) per day.

The rapidity of the movement increased as we drew farther to the south. It became especially rapid towards the end of the drift, in January and February. For example, from the Pole to lat. 85° N. (from May to October) the average rate of movement was 2·7 miles a day. From lat. 85° to 80° N. (from October to January) the speed of the drift increased to 4·6 miles a day. In January the average speed had already risen to 11·5 miles, and in February to 12·3 miles a day.

What causes the movement of the ice in the region of the polar basin investigated by us ? A preliminary examination of our observations shows that the ice drifts by the action of the wind blowing in a given spot ; yet at the same time it has a continuous movement (directed in general to the south) which is independent of the local wind. Thus, in calm periods the ice moves to the south. A wind blowing from the north will speed up this movement. Southern winds will retard or even overcome it, and drive the ice to the north. The speed of the ice movement independent of the local wind was about a mile a day near the Pole. Farther to the south it gradually increased, reaching 5–7 miles per day between the 75th and 70th parallels.

On this systematic movement is superimposed the drift caused by the wind blowing in the given spot. The wind is powerless to draw the ice in the direction in which it is blowing. Preventing this is the law by which a body moving on the surface of the earth in the northern hemisphere is inclined to deviate to the right of the direction of its original movement. The ice, obeying this law, deviates to the right of the direction of the wind at an angle of about 40°. The speed of movement of the ice naturally depends on the velocity of the wind. It is interesting to note that their interaction—the "power of the wind to drive the ice"—was not uniform during the whole of our course. Near the Pole the wind drove the ice with a speed equal approximately to one- to two-hundredths of the velocity of the blowing wind. At the end of the drift the action of the wind increased in effectiveness.

---

* Received through the Soviet Union Year Book Press Service, 623–624 Grand Buildings, Trafalgar Square, W.C 2.

What causes the movement of the ice southwards independently of the local wind ? It seems simplest to assume the existence in the Arctic Ocean of a surface current which draws the ice. However, the rotatory observations, which will be dealt with in detail later, reveal the opposite. It is not the water which draws the ice, but the moving ice which draws after it the upper layers of the water. Evidently the general weather regime in the polar basin results in the prevalence of northerly and north-westerly winds (again we are calculating the direction in relation to the Greenwich meridian). These winds, predominating over a vast stretch, create a general flow of the ice towards the Greenland Sea.

Observations of currents arising in surface layers of the sea from the action of the drift of the ice were carried out by means of simultaneously lowering two rotators to different depths. The observations were made in series of five to six layers. Forty series of this kind were made. It appears that the ice draws only the uppermost surface layer of water. For example, with an ice-drift having a speed of 0·1–0·15 metre per second, the drift current is obvious at depths of 25–35 metres, and only on rare occasions does it affect the water down to 50 metres. The speed of the current decreases quickly with increasing depths. Whereas at a depth of 5 metres (two metres from the lower surface of the ice) the speed of the current fluctuates from 65 to 100 per cent of the speed of the drift, at a depth of 20 metres the speed of the current does not generally exceed 20–30 per cent of the speed of the ice-drift.

The drift current in the upper layers of the water sets in very quickly after the ice drift has begun, but it ceases as rapidly when the ice drift stops. A rapid and prolonged drift of the ice in any one direction draws after it a considerable quantity of water from the surface layer. An inflow of water follows from adjoining regions to replace it. A reverse current sets in to compensate for the movement of the surface waters from the given region. More often the reverse current is observable immediately underneath the surface layer of water drawn by the drift, that is, at a depth of 50–75 metres. However, during prolonged and rapid drifts, the reverse current embraces a considerably thicker layer, 35–125 metres.

In contrast to the drift current of the surface layer, the reverse current sets in after an appreciable lapse of time following the start of the drift of the ice—usually 12–36 hours. It reaches its maximum speed even later still, not infrequently only after the drift of the ice, which set the masses of water into motion, has ceased. Not infrequently, too, the reverse current continues for a long time, sometimes for several days, after the ice drift has stopped. For example, after a rapid drift to the south-east during August 10–13, the reverse current was observed at a depth of 75 metres up to August 19, that is, five days after the drift had ceased.

Measurements of depth were carried out by the help of a specially constructed deep-water hand-worked winch, equipped with a brake of the Lucas type. Altogether thirty-three observations were made, of which fourteen were at depths of more than 3,000 metres.

Starting from the Pole, up to lat. 86° 40′ our icefloe drifted over a deep hollow with an extremely sloping bottom of a depth of 4,300–4,400 metres. The greatest depth here appeared to be 4,395 metres (position lat. 88° 41′ N., long. 10° W.). Then the bottom commenced to rise—unevenly, with big jumps in depths, varying from 300 to 500 metres over a distance of 30 miles. In this region (up to the 84th parallel) the depths varied from 3,500 to 4,050 metres. At lat. 83° 56′ N., long. 0° 47′ E., we discovered a submarine elevation. The depth here was 2,380 metres. Farther on, from lat. 83° 30′ N. to 81° 50′ N., we again came to a depth of more than 3,000 metres. The greatest depth in this region exceeded 4,160 metres (lat. 81° 53′, long. 6° W.). The whole of the cable then on the drum was paid out but failed to reach the bottom. The existence of great depths in this region is of special interest in view of their proximity to Greenland. It was generally supposed that the depths here were those of the continental slope ; actually there were deep hollows situated only forty miles from the North East Foreland.

The next measurement (at lat. 81° N., long. 6° 50′ W.) was carried out on the so-called Nansen threshold. The depth here was 1,420 metres. We know that it used to be supposed that here, between Spitsbergen and the North East Foreland, the sea bed rose to within a thousand metres of the surface, thus dividing the Arctic Ocean from the Greenland Sea. However, we maintain that the depth here is no less than 1,300–1,400 metres, and that, quite probably, the depths in the central parts of the Nansen threshold reach 2,000 metres.

In the Greenland Sea the icefloe drifted over the coastal platform. Here the depths were 160–250 metres, reaching 320 metres in one spot only.

Samples of the bed were taken at eight northern soundings with the aid of a scoop. The ground in the deep hollow of the polar basin is composed of oceanic silt of a reddish-brown colour. Under this layer of silt is grey silt. We have brought samples of these deposits with us for further analysis.

The thirty-eight hydrological soundings made by us during the period of the drift represent the two hydrological sections, from the 89th parallel to Greenland, and in the Greenland Sea to the 76th parallel.

During his drift in the *Fram*, Nansen discovered under a comparatively thin layer of cold Arctic water a powerful layer of water of Atlantic origin with positive temperatures. In 1935 the same water was encountered to the north-west of Severnaya Zemlya (Northern Land) by the Ushakov High Latitude Expedition in the *Sadko*. Lastly, the expedition in the *Krasin* in the same year, 1935, also discovered water with a positive temperature to the north of Herald Island. But all these instances relate to the borders of the polar basin, and it might have been presumed that the Atlantic water penetrating to the Arctic Ocean was pressed by the deflective action of the earth's rotation to the right, towards the Eurasian mainland. However, our investigations have shown that the Atlantic water flowing into the Arctic Ocean between Greenland and Spitsbergen in a powerful current reaches the Pole, apparently spreading extensively through the greater part of the polar basin.

At all the soundings, under the comparatively thin layer of cold Arctic water with negative temperatures common to polar seas, a layer was found with positive temperatures and of considerably greater density than the water of the surface layers.

At soundings taken to the north of the 86th parallel, the upper negative isotherm is at 250 metres, the lower at 750 metres. Thus the thickness of the layer of water with positive temperatures in the region near the Pole reaches 500 metres. The maximum temperature in this region is 0·77° C. (at a depth of 400 metres). Farther on, to the south, between the 86th and 85th parallels, the negative isotherms separate—the upper rising to a depth of 200 metres and the lower dropping somewhat deeper—to 750 metres. Thus the thickness of the layer of Atlantic water here increases. There is an increase also in the temperature of the water: plus 1° C. at a depth of 400 metres, and 0·88° at a depth of 250 metres. Farther to the south the layer of Atlantic water becomes more powerful, and the maximum temperature rose to 1·72° C. (at a depth of 250–300 metres).

At the 81st parallel we came out to the edge of the current of Atlantic water. The isotherms converged sharply as we drew nearer to the North East Foreland of Greenland.

The deep layers were filled with water of temperatures and salinity common to oceanic depths. In the layer at the bottom we observed somewhat higher temperatures—common to all deep oceanic hollows. At a depth of 4,390 metres the temperature of the water reached − 0·63° C. The cause of this rise in the temperature of the water of the bottom layer lies in the warmth flowing from the earth's crust, and also in the bacterial processes of decomposition of organic remains which have sunk to great depths. The heat generated during these processes may cause the rise in the temperature of the water.

With twenty-two hydrological soundings samples of plankton were taken at different depths. As we know, Nansen advanced the theory that the ocean was very poor in organic life in high latitudes. He believed the cause of this to be that under conditions of an ocean completely covered with fields of solid ice even in summer, plant plankton cannot develop owing to the absence of light, and as plant plankton, in the last resort, is the basic nourishment of the entire animal population of the sea, then naturally the higher animals, too, particularly sea animals, could not exist here. But this hypothesis has turned out to be incorrect. During the course of an entire month (August) our observations showed that under the solid ice, in the upper layers of the sea, an intensive development took place of microscopic sea-weed, constituting that 'florescence' of plankton, observable in the 'biological' spring in seas of more southern latitudes. This 'florescence' begins at the end of the short polar summer when all the snow has melted from the surface of the ice, which has also perceptibly suffered from the thaw. Evidently, at that time, the intensity of light penetrating to the water through the melting ice is sufficient for the development of seaweed.

The quantity of plant plankton was estimated by the quantity of chlorophyll, which was determined by a spectrocolorimeter. If plant plankton was able to develop here, then naturally it was possible for animal life to exist; and certainly from all depths of the ocean—even from a depth of 3,000 metres—the plankton net brought up examples of different species of animal plankton.

If plankton exists, it is also possible for the higher animals to exist, and at the 88th parallel we saw a hare, a polar bear with two cubs, not to mention seagulls, which visited our camp on more than one occasion. The hypothesis that no life exists near the Pole must therefore be assumed to be wrong.

Measurements of the force of gravity were made by us at twenty-two points, situated between the

89th and 74th parallels. At present, we have provisionally calculated thirteen of these gravitational points. The last points it was impossible to calculate, as the increasing rapidity of the drift towards the end compelled us to carry out all observations much more frequently and to postpone their working up. The difference between our results and the values given for the same points by the international formula is as follows. At the 89th parallel the observations of the force of gravity practically coincided with the theoretical values. From the 88th to the 84th parallel stretches a field of positive anomaly. Here our measurements give a value greater by approximately 60 mgm. than was supposed. From the 84th to the 83rd parallel is observed a sharp decline in the measured value. At the 83rd parallel the anomaly already has a negative significance of approximately — 30 mgm. Evidently this jump is closely connected with the relief of the bed. Here, as it happens, a rise to the shallow waters at the coasts of Greenland commences.

The object of our magnetic measurements was to elucidate the geographical distribution of the elements of terrestrial magnetism over the course of the drift : inclination, declination and horizontal intensity. For this we made our measurements with the help of a magnetic theodolite. During our stay on the ice floe, we made fifty-five series of determinations of inclinations and horizontal intensity, and thirty-six measurements of declinations. The measurements were taken right up to lat. 84° N. Farther on, the icefloe began to rotate so rapidly that it was impossible to use the variometers. It became necessary to take more frequent measurements in order, so far as possible, to weaken the effect of the magnetic disturbances. The measurements show that over the entire stretch of our drift there were no considerable magnetic anomalies.

With the setting in of the darkness at the beginning of October, we began to make hourly visual observations of the northern lights, and continued these until February 9.

Meteorological observations were carried out by us four times a day. We measured the temperature of the air, pressure (by two aneroids), humidity (in the summer by psychrometer; from August, during the periods of frosts, by a hair hygrometer of the Kuznetsov type), direction and velocity of the wind. At first all the four daily measurements of wind velocity were carried out by an anemometer. Later, when one of our anemometers went out of action, we used the remaining one only once a day, and the other three times determined the velocity of the wind visually. Up to the middle of October we have an unbroken record of wind velocity taken by the anemograph. The barograph and thermograph kept on functioning the whole time.

The rapid drift of the ice permitted us to spend only four summer months in the region of the cold polar cap, the investigation of which is of so great an interest to meteorology. It can now be said with certitude that the weather in this region is considerably calmer than on the borders of the Arctic Ocean. For example, we never observed any very strong winds there, though we did not find the steady anticyclonic regime supposed to exist in that region. Our observations were communicated to the mainland daily.

The foregoing is a provisional account of the results of our scientific work. Immediately on our return home we shall begin to work up our material, so as to give a complete account of the investigations carried out by our expedition to the North Pole.

Oil from Coal*

THE report of the Sub-committee on Oil from Coal of the Committee of Imperial Defence serves a useful purpose, although nothing new is disclosed. Unless unexpected discoveries of petroleum should result from the exploratory work conducted by oil companies as an outcome of the recent Petroleum Act, Great Britain has only one alternative to importing practically the whole of its oil supplies : that is, the large-scale conversion of coal into oil by hydrogenation or synthesis, processes which are still very costly in both capital and operation. Oil and motor spirit are produced in small proportions as by-products from the carbonization industries, but such sources are not capable of indefinite expansion, since their industrial stability is dependent upon adequate markets for the main products—coke of various kinds or gas. They were, however, stimulated by the guaranteed preference at the rate of 4*d*. a gallon for ten years which has operated in favour of home-produced motor spirit since the Act of 1934. Although only 4*d*. per gallon is guaranteed by this Act, the actual preference which has been in operation since 1934 has been 8*d*., but this involves a shortening of the period during which the guarantee is effective. The report recommends that the *guarantee* should be increased to 8*d*. a gallon and remain in operation until 1950, and that it should be extended to include diesel oil used in motor vehicles.

---

* Committee of Imperial Defence. Sub-Committee on Oil from Coal: Report (Cmd. 5665) Pp. 71 (London: H.M. Stationery Office, 1938.) 1*s* 3*d*. net.

It might be feared that this extension would involve a loss of revenue, but the consumption of oil and motor spirit is increasing so rapidly that any expansion of the various industries producing oil from coal would probably, at most, only provide for the increase, and could take place without reducing the present imports.

The Committee includes in its report a very welcome discussion of the position in time of war, and this probably forms its most valuable contribution. Much confusion has arisen in the past from the statements of parties interested in particular processes, or from well-meaning individuals who have based their deductions on incomplete knowledge. Even should carbonization processes expand to a degree wildly in excess of anything at present appearing commercially practicable, the supplies of motor spirit forthcoming would form only a small fraction of those needed in times of national emergency. The only methods which can be looked to as potential sources of large supplies of oil are hydrogenation and the Fischer or similar synthetic processes, where oil is the main product and is independent of the markets for coke and gas.

At present, only about 7 per cent of the motor spirit consumed in Great Britain is home-produced, and the home production of fuel oil, lubricating oil, etc., is negligible. An enormous expansion, involving the erection of many large plants, with consequent heavy capital expenditure, would thus be required to meet even peace-time demands. If such plants were put into operation, the consequent decrease in imported oil would eventually result in a considerable diminution of our sea transport facilities and make the possibility of import during war much more difficult. Moreover, large oil production plants would be extremely vulnerable to air attacks; and the man-power and supplies of coal needed for their operation, although an advantage in times of peace, might not be easy to provide when the fighting and munitions supply services were demanding all the men available. An interesting comparison is made between the capital cost of a plant with a yearly output of 150,000 tons of motor spirit (about £8,000,000) and the thirty-two tankers which could be built for the same sum, which, even if making only five voyages yearly, could carry 1,800,000 tons, or twelve times the output of the hydrogenation plant.

For these and other reasons, the Committee confirms the opinions already formed by those who have studied the subject impartially, that "in general a policy of depending on imported supplies with adequate storage is the most reliable and economical means of providing for an emergency".

Although in general agreement with the remarks of the Committee concerning low-temperature carbonization, the writer thinks it a pity that evidence in this field should have been taken only from the Low Temperature Distillers' Association of Great Britain, Ltd. In a subject which is still so experimental as low-temperature carbonization, an association of this character cannot be altogether representative, for, since it is not likely to welcome newcomers to introduce additional competition, much valuable data must be withheld from it. The Committee has, however, doubtless been in close touch with the Government Departments concerned in the matter.

C. H. LANDER.

Archæological Discovery in Britain, 1933-38

IN arranging an exhibition at the Institute of Archæology of the University of London to illustrate the achievement of field archæology in Great Britain and Northern Ireland during the five years 1933–38, the promoters have provided a conspectus of results which is continuous with those of the two exhibitions of a similar character held in 1929 and 1932, the latter in conjunction with the International Congress of Pre- and Protohistoric Sciences, which met in London in that year. The inevitable comparison demonstrates the very considerable advance made by archæological studies in the interval, and its direction.

The most striking feature in such a comparison is the increase in size of the present exhibition. This is not merely a matter of the total of exhibits, but also extends to the number of sites represented. For this the more efficient organization now possible is in part responsible; but unquestionably the decisive factors have been the growing activities of archæologists, and in no small degree an increased and more widely spread interest among a public which is prepared to support archæological excavation, financially and otherwise. For this part credit must be allowed to the Office of Works, which in the exercise of its statutory duties has stimulated local authorities, local museums, local societies and a local public to preserve their ancient monuments, or where that has been impossible, to obtain from them such information relating to the past as they can be made to render up by skilled investigation before the evidence is obliterated. Among the more salient instances of such interest, of which the results are to be seen here, is the Old Jewry Wall site at Leicester, and the Belgic and Romano-British site at Colchester, whence comes the notable evidence of the factory of 'Colchester' ware, or local Samian.

Dr. R. E. Mortimer Wheeler, director of the Institute, in a short but illuminating introduction to the catalogue of the exhibition, regards it as demonstrating the extension of archæological fieldwork to provinces other than the Romano-British studies which, following the pre-War Haverfield tradition, dominated the early post-War years. This, no doubt, is true in some measure, but needs qualification. What is especially notable is not so much the change in the orientation of archæological studies as the increase in the number of professional or highly trained archæologists, whose interests and services are now available for investigation in the wider field, which previously was not so much neglected as for a variety of reasons left to the investigator who, though experienced and frequently of advanced technical skill, was not professionally trained. The effect of this change in the qualification of personnel is to be seen on all sides. Without risking invidious distinction, mention may be made of instructive examples in the mesolithic exhibits from Sussex, in which there is profound knowledge and trained experience behind the arrangement and classification of the finds from the pit-dwelling site at Selmeston, unique at present in British scientific investigation, and of the Tardenoisian industry from Horsham, for both of which Dr. J. G. D. Clark is responsible. The work undertaken by Mr. Alexander Keiller and the Morven Institute of Archæological Research at Avebury lends further support to the contention, as also does the material drawn from bronze and early iron age sites in Sussex, Gloucester and Wales.

It is a further mark of the trained habit of mind that help from other sciences is being sought in an increasing degree to give objectivity to the findings of the archæologist. The evidence of geology and palæontology on broad lines has always served the excavator; but to this are now added intensive investigations in geology, climatology, palæobotany, which call for the employment of laboratory methods. Prof. F. E. Zeuner, the distinguished authority on prehistoric chronology, who is now attached to the staff of the Institute, stages an exhibit of the methods of geochronology, in which he shows how mechanical and chemical analysis of soils and gravels can be made to show changes of climate and geological conditions, and demonstrates the tree-ring method of time measurement, which has been used extensively in American archæology. Two interesting and instructive examples of the use of analysis and experiment in field work appear among the exhibits from archæological sites. The first comes from Wales and establishes the earliest recorded use of coal as fuel in Britain in a bronze age cremated urn burial from the Simonston Cairn, near Bridgend, Glamorgan, excavated by Sir Cyril and Lady Fox. The second is included in material, also from Wales, excavated by Mr. B. N. St. J. O'Neil from Fridd Faldwyn Camp, Montgomery. It is an example of vitrification, which is compared with similar vitrified rock from a hill-fort in Bute, and also with vitrified material experimentally produced by Mr. Wallace Thorneycroft, who has thus solved a puzzle of long standing among Scottish archæologists.

Before leaving the subject of archæological technique, attention may be directed to the nucleus of a collection of photographs taken from the air for which Major G. W. G. Allen is responsible. Such photographs are now familiar as an instrument of survey and discovery; but the technique of ground photography is less widely appreciated. Enlarged photographs arranged by Mr. M. B. Cookson illustrate the varied points of technical detail recorded by skilled manipulation of the camera. Technical considerations apart, the photographs of interments of the defenders of Maiden Castle, Dorchester, are intensely impressive; while those of the recently reported investigation of the methods of construction of Hadrian's Wall are of special interest at the moment.

Finally, as an example of more or less straightforward excavation, carried out with a patience that is unlimited, which are the fundamentals of archæological method, reference may be made to Mr. A. Leslie Armstrong's excavation of the Pin Hole Cave, Creswell Crags, Derbyshire, in which twelve years' work has penetrated through twenty feet of deposits and has brought to light relics of three phases of Mousterian, separated by two glacial phases or events, of Solutrean and of Aurignacian, the last including an engraving of a man masked for a ceremonial dance unique in Britain.

It may seem that in directing attention to the more salient features of the exhibition, which mark progress and direction in British archæology, too little has been said of individual exhibits. This is not due to any lack of interest. While there is no section which does not repay study, those which cover the early iron age and more particularly the period immediately before the Roman invasion, open up a field which a few years ago was unmapped. All sections alike in quality and number of exhibits testify not only to the skill of the investigators, but also to the value of this branch of scientific research in Britain as a source of material for the advancement of knowledge of man's cultural development and history.

Dr. Wheeler points out that recent development in archæological studies implies an elaboration of technique rather than a change of heart, while the position of General Pitt-Rivers as the founder of scientific archæology remains unchallenged. So long as this obtains, there is the less need for Dr. Wheeler's admonition to the archæologist to bear in mind that he is not merely a mechanic, but is also a student of humanity. If there be any danger, Dr. Wheeler's own excavations of Verulamium and Maiden Castle, which hold an outstanding position in the exhibition, spur his colleagues to emulation and guide them along the right path.

Obituary Notice

Sir Harcourt Butler, G.C.S.I., G.C.I.E.

BY the death of Sir Harcourt Butler, termed one of the greatest administrators in India of his day, which took place on March 2 at the age of sixty-eight years, oriental studies in the University of London have lost one of their strongest supporters.

Spencer Harcourt Butler was the second son of Mr. Spencer Percival Butler, conveyancing counsel to the Office of Works, a nephew of Dr. H. M. Butler, Master of Trinity College, Cambridge, and a brother of Sir Montagu Butler, now Master of Pembroke College, Cambridge. Born on August 1, 1869, Harcourt Butler was educated at Harrow and Balliol College, Oxford. He passed into the Indian Civil Service in 1888 and went to the United Provinces of Agra and Oudh, where he remained and served with conspicuous success until 1907, when he was chosen by Lord Minto to act as secretary of the Foreign Department, an office which brought him into close personal touch with the native princes. In 1910, Butler was appointed to the newly created post of education member in charge of sanitation, local self-government, archæology and other minor branches of public works. Butler took up the administration of these heterogeneous activities with vigour.

In 1915, Sir Harcourt (as he had become three years before) was transferred to Rangoon as Lieutenant-Governor of Burma. One of his early achievements was to raise a substantial sum for the provision of a teaching university in Rangoon to take the place of the colleges previously affiliated to Calcutta. In 1917 he returned to his old Province to take office as lieutenant-governor; but in 1923 he returned to Burma to become Governor under the new system inaugurated in 1919.

Butler's activities during this second term of office in Burma have met with criticism in two directions. He had already shown enthusiasm for education both in Rangoon and previously in India, where he had encouraged the foundation of universities at Benares for Hindus and at Aligarh for Moslems; while in his time in Oudh the University of Lucknow had been created and the University of Allahabad had been reconstructed. On his return to Rangoon, he found that his scheme for a university was languishing. He brought forward fresh legislation, and schemes were framed for raising money. Both measures met with much opposition and even aroused some personal animosity.

In another direction, Butler's actions have been regarded as not in the best interests of those he intended to serve. This was the abolition of slavery and human sacrifice in the land of the savage Nagas known as the Triangle, the then unadministered territory bordering on the Hukwang Valley. Butler was successful in stamping out these practises; but while they are repugnant to civilized ideas and not permissible under British administration, the anthropologist has to recognize that the abolition of slavery, at least without adequate substitute, economically has had a damaging effect in forcing land out of cultivation and reacting adversely on the morale of the tribes.

On leaving Rangoon in 1927, Butler was appointed chairman of the Indian States Committee to report on the relationship between the Paramount Power and the States. The report issued in 1929 proved a standard of reference on the question of federation in the Round Table Conference which followed.

On his return to England, among numerous other activities Butler accepted in 1931 the chairmanship of the Governing Body of the School of Oriental Studies, and took a prominent part in the arrangements for the new quarters of the School in Bloomsbury, now approaching completion. Among the numerous honours bestowed upon Sir Harcourt Butler were honorary doctorates from the University of Oxford and several of the Indian universities.

WE regret to announce the following deaths:

Mr. E. A. S. Fawcett, C.B., chief engineer to the Ministry of Health from 1921 until 1930, on April 1, aged sixty-nine years.

Mr. Edward Meyrick, F.R.S., assistant master at Marlborough College from 1887 until 1914, an authority on Australian Lepidoptera, on April 1.

Mr. T. H. Digges La Touche, formerly of the Geological Survey of India, on March 30, aged eighty-two years.

News and Views

An Extra-galactic Star Cluster

IT is reported by the New York correspondent of *The Times* that Dr. Harlow Shapley has announced the discovery of a great cluster of stars in the southern constellation Sculptor. The discovery was accidental, the cluster being photographed with the 60-inch reflector at the Harvard Southern Station at Mazelspoort, near Bloemfontein, South Africa, on a very clear night with a highly sensitive plate. If the median absolute magnitude of the stars photographed be assumed to be $-1\cdot5$, the apparent magnitude being about $+18$, it follows that the distance of the cluster is about 250,000 light-years. This places it well beyond the limits of our galactic system, the distance being more than double that of the Magellanic Clouds, and adds another to the known systems that are relatively near to our galactic system. The angular diameter of the cluster is greater than 1° and the linear diameter is estimated to be about 6,500 light-years, which indicates a size comparable with the Small Magellanic Cloud. The cluster is oval-shaped, unlike the clusters in our galactic system, which are globular. It is stated that there are about 10,000 stars in the cluster between the brightest stars and the dimmest that have yet been counted. The Magellanic Clouds are rich in stars of very high luminosity. The Sculptor cluster would undoubtedly have been discovered earlier, if it had contained such stars. It is probable that, when further photographs are available, Cepheid variables will be discovered in it and the study of their light variations will enable a more accurate determination of the distance of the cluster to be made.

Bequests for Research in Marine Biology

MR. EDWARD THOMAS BROWNE, a governor of the Marine Biological Association, who died on December 10, 1937, was for many years the leading authority in Great Britain on medusæ and other cœlenterates. Under his will, a number of valuable bequests are made to different bodies for the benefit of scientific research. The residue of his estate, estimated to amount to some £50,000, goes to the Royal Society to form a fund for the promotion of marine expeditions or individual research on marine biology. In addition, £6,725, together with scientific books, instruments and apparatus, are left to the Marine Biological Association for special purposes in connexion with the Plymouth Laboratory, £15,000 to Queen's College, Oxford, for a research fellowship and a scholarship in biology, and £5,000 to University College, London, for a postgraduate research studentship in zoology, in memory of his wife. After graduating at Oxford, Mr. Browne took up the serious study of zoology under the late Prof. W. F. R. Weldon at University College, London, in 1891, and remained at the College as a research worker until 1909. His summers were spent at different marine laboratories, Port Erin, Plymouth, Millport and at other places suitable for his work, including Valencia, Falmouth and the Scilly Isles. A monograph on the British medusæ is nearly completed, and provision is made in his will for its publication. He examined and reported on the medusæ from many foreign collections, especially from expeditions, including those from the Maldive and Laccadive Archipelago, the Gulf of Manaar, the Indian Ocean, the Suez Canal, the Scottish Antarctic Expedition, the British National Antarctic Expedition, the Falkland Islands, Norway and Spitsbergen. Browne was a very thorough and careful worker, with a complete knowledge of the literature of the groups in which he specialized. He gave great assistance both financially and, as a member of their respective councils, in the administration of the scientific societies in which he was interested, including the Royal Microscopical Society and the Quekett Club.

Soviet Awards for North Polar Expedition

ON p. 629 of this issue we print an account of the preliminary scientific results obtained by the Russian men of science who occupied the drifting north polar station. The Riga correspondent of *The Times* states that the following awards have been made to members of the expedition: M. Ivan Papanin, already a 'Hero of the Soviet Union' and a member of the Order of Lenin, has received the second class of that order and a present of 30,000 roubles, and has been appointed first deputy chief of arctic navigation (of which Prof. Otto Schmidt is chief). MM. Krenkel, Shirshoff and Fedoroff have been decorated with the Order of Lenin, awarded the title of 'Hero of the Soviet Union', and also received 30,000 roubles each. The captains of the *Taimyr*, *Murman* and *Murmanets*, and M. Ostaltseff, who conducted the relief expedition on board the *Taimyr*, and the airman, M. Vlasoff, have been decorated with the Order of Lenin and received 10,000 roubles each; and 118 others who took part in organizing the expedition to the North Pole and the rescue of the ice-floe party have been awarded various other decorations and sums of money.

Bronze Age Cairns in Glamorganshire

Two cairns of the bronze age, adjoining the village of Coity, near Bridgend, Glamorganshire, excavated by Sir Cyril Fox, director of the National Museum of Wales, and Lady Fox have made notable additions to the records of British archæology. The Simondston Cairn affords evidence of the earliest known use of coal as fuel in the British Isles. In the second, the Pond Cairn, was found a pit containing the remains of vegetation and grains of wheat and barley, believed to be the first food grains of the bronze age recorded in southern Britain. The excavations were described before the Society of Antiquaries of London by Sir Cyril Fox on March 31. The Simondston Cairn is of the normal highland Early Bronze Age type and contains burials of two adults and a child, dating from about 1600 B.C. In the southern rim of the cairn were five cremation burials of about a generation later. It was in one of these that the traces of coal were identified. The nearest outcrop of coal is about a mile and a half away. The second cairn, Pond Cairn, lies half a mile away from Simondston and is on a lower level. It is of a very unusual type both as regards its structure and the ritual acts involved in the construction. Near the centre was a rock-cut pit, probably dedicatory, which was filled with stones and contained the scattered burnt bones of a child. The primary burial was an urn of about 1300 B.C. which was covered with a heap of stones and a vertical-sided turf stack. A basin with a projection, phallic in plan, and lined with charcoal, fronted the urn. Around the turf stack was a continuous cairn ring, sixty feet in diameter, with an inner wall face and outer kerb. The space between the ring and the stack was scattered over with charcoal, and had been trodden hard, presumably in some ceremonial movement. Later the inner face of the ring was broken and the pit, to which reference is made above, was dug. It was covered with a pile of stones, linking the ring with the stack. The Pond Cairn is comparable with examples in Devon. With the secondary deposits at Simondston it probably represents an intrusion across the Severn Sea into the Glamorgan plain.

Roman Dorchester

Resumed excavation on behalf of the Dorset Archæological Society on the site at Colliton Park, Dorchester, which has been purchased by the County Council for the erection of a shire hall, has already produced several discoveries (*The Times*, March 3). It will be remembered that last year, when excavation began, a large Roman town house was discovered belonging to the Roman city of Durnovaria which underlies the modern town. This has been completely excavated and is to be preserved intact by the County Council. Trial trenches have now revealed that four important Roman buildings underlie the area upon which the shire hall is to be erected. These it is hoped to examine. A well-made path of cobble flints leading to the door of the house has been brought to light. It overlies an earlier wooden cookhouse, furnished with an oven. A large pit was also found. This was circular in plan and lined with blocks of stone. It is fourteen feet in diameter and sixteen feet deep. A passage to the west leads to the Roman town wall. Excavations will be continued for a further period of at least three months.

Jungfraujoch Research Party

At the end of this month Mr. G. Seligman, author of "Snow Structure and Ski Fields", will take a party of scientific workers to the Jungfraujoch Research Institute in Switzerland to undertake scientific research work on glaciers. This will be the first British expedition ever to spend its whole time studying glaciological problems, and it will form a continuation of Mr. Seligman's previous researches on the nature of snow. The party will spend five months at the Institute, at a height of more than 11,000 feet, and will consist of: Mr. T. P. Hughes, of the Physical-Chemical Laboratory, Cambridge—physicist; Mr. M. F. Perutz, of the Crystallographic Laboratory, Cambridge—crystallographer; Mr. A. E. Benfield, of the Department of Geodesy and Geophysics, Cambridge, and Mr. E. A. Ferguson, of the Department of Geography, Cambridge—assistants. The chief problem to be investigated will be the transition of firn into glacier ice, but other problems, particularly those which may have some bearing on the main question, will be investigated, notably the movement of glaciers, the formation of ice-bands and the connexion, if any, between those in the névé regions and those near the snout of the glacier. In addition, Mr. Hughes will carry out certain experiments on the friction of solid bodies on ice, in connexion with his work at the Physical-Chemical Laboratory, Cambridge. Mr. Seligman has been granted a Leverhulme Research Fellowship for the purpose of this research, and the expedition is also supported by the Royal Geographical Society, the Ski Club of Great Britain and the Alpine Ski Club.

Changing Conceptions of Education

At a public meeting of the Derbyshire County Association of the National Union of Teachers on March 26, Mr. A. E. Henshall, education secretary of the Union, spoke on present-day teachers' aims and attitudes as contrasted with those of their predecessors. The attitudes established by the notorious payment-by-results system persisted long after its abolition, but to-day there is fairly general acceptance of the view that the teacher is concerned before everything else with the welfare of the individual child, considered as a person destined in due course to contribute to the welfare of the community as a citizen of a democratic State. It follows, at least in theory, that teachers of children in all stages in every kind of school—infants, junior, senior, central, secondary—are united in a single task and owe it to themselves and their charges that they should co-operate as fellow workers in a unitary service. To promote such co-operation by providing convenient occasions for getting together and comparing notes is an important function of the local associations of the National Union. Mr. Henshall stressed the pioneer role of the new senior schools and warned their teachers against sacrificing their comparative freedom in a misguided effort to rival the secondary schools. With equal emphasis he insisted on the importance of the junior schools, the teachers of which should be regarded as having a status not inferior to that of senior school teachers.

Social Services of the League of Nations

In an article entitled "The Non-Political Value of the League" contributed to the *Quarterly Review* for

January, Capt. A. L. Kennedy gives an admirable survey of the services rendered by the League of Nations technical organizations in non-political fields. He stresses the value of the resettlement of populations in Greece under the League Commission as a contribution to European peace and indicates the need for dealing with questions of refugees and minorities which still persists. In regard to opium, the co-operation established at Geneva has resulted in a central office which maintains supervision over a complete branch of economic activity, from the import of the raw material to the consumption of the manufactured article and in checking its transport from one country to another. This achievement has, however, set the League the even harder task of suppressing the illegitimate traffic which still flourishes to a serious extent and also the task of controlling the raw material. Again, the League has provided a central body for collating and directing measures against the traffic in women and children, and it has every claim to be regarded as the world's ministry of health, not only co-ordinating health work in different countries, as well as research and standardization but also, as in the Singapore Epidemiological Intelligence Bureau, providing an intelligence service for the prevention of epidemics. Capt. Kennedy writes appreciatively of services rendered to China before the onslaught of Japan occurred as well as to the reconstruction work in Austria, the work of the Mandates Commission and of the International Labour Office and the Permanent Court of International Justice. This well-balanced assembly of facts leaves no room for doubt that if the failure to use the League in the political sphere led to its abandonment, we should require an exactly similar organization to carry on its present non-political activities if both nations and individuals are not to be deprived of services which have given and are giving them relief from want and suffering, higher moral and material standards and opportunities of a useful life.
